HOMOTOPY THEORY OF LABELLED SYMMETRIC PRECUBICAL SETS

PHILIPPE GAUCHER

Abstract. This paper is the third paper of a series devoted to higher dimensional transition systems. It is proved that there exists a model category of labelled symmetric precubical sets which is Quillen equivalent to the Bousfield localization of the left determined model category of cubical transition systems by the cubification functor. The realization functor from labelled symmetric precubical sets to cubical transition systems is not a left Quillen functor: it is only a left adjoint. It is proved that the two model categories are related to each other by a zig-zag of Quillen equivalences of length two. The class of cofibrations of this new model category structure is strictly larger than the class of monomorphisms. The weak equivalences are closely related to bisimulation. Similar results are obtained by restricting the constructions to the labelled symmetric precubical sets satisfying the HDA paradigm.

1. Introduction

Presentation of the paper. This paper is the third paper of a series of papers devoted to the homotopy theory of higher dimensional transition systems. The first appearance of higher dimensional transition systems goes back to [CS96]. The motivation for introducing this kind of object is the geometric approach of concurrency in computer science. Like the model of labelled symmetric precubical set, it can be used for modelling concurrency [Gou02] [Gau10a] [Gau08] [Gau10b]. Unlike them, it does not focus on the notion of *face operator* between higher dimensional cubes, but rather on the notion of *higher dimensional transition.* The first appearance of geometric models of concurrency goes back to [Dij68] [Pra91] [Gun94]

1991 *Mathematics Subject Classification.* 18C35,18G55,55U35,68Q85.

Key words and phrases. precubical set, higher dimensional transition system, locally presentable category, topological category, combinatorial model category, Bousfield localization.

[Gou03] [VG06] but it is really not possible to give an exhaustive list of references for this subject because this field of research is growing very fast.

The first paper of the series [Gau10b] was devoted to introducing a more convenient formalism to deal with higher dimensional transition systems. More precisely, the category of weak higher dimensional transition systems (weak HDTS) was introduced (Definition 3.2). It enjoys a lot of very nice properties (topological, locally finitely presentable). The category of Cattani-Sassone higher dimensional transition systems was interpreted as a full reflective subcategory of the category of weak HDTS [Gau10b, Corollary 5.7]. And it was proved in [Gau10b, Theorem 11.6] that the categorical localization of the category of Cattani-Sassone higher dimensional transition systems by the cubification functor (Definition 8.8) is equivalent to a full reflective subcategory of that of labelled symmetric precubical sets (Definition 5.5).

The second paper of the series [Gau11] was devoted to the study of the homotopy theory of cubical transition systems, i.e. the weak HDTS which are equal to the union of their subcubes (Definition 3.8). This full coreflective subcategory of that of weak HDTS contains all examples coming from computer science even if the topological structure of the larger category of weak HDTS keeps playing an important role in the development of this theory. A left determined model category was constructed [Gau11, Corollary 6.8] and the Bousfield localization with respect to the cubification functor was studied [Gau11, Section 8]. The link with bisimulation was sketched as well.

This third paper goes back to the link between labelled symmetric precubical sets and cubical transition systems. One of the main results of this paper is that a new model category structure is constructed on the category of labelled symmetric precubical sets (Theorem 6.8). And it is proved in Theorem 8.9 that there exists a Bousfield localization which is Quillen equivalent to the model category structure of cubical transition systems introduced in [Gau11] (not the left determined one, but its Bousfield localization by the cubification functor, which is studied in [Gau11, Section 8]). Theorem 9.6 is a similar theorem after restriction to the labelled symmetric precubical sets satisfying the HDA paradigm. Unfortunately, almost nothing is known about these Bousfield localizations. Surprisingly, the realization functor from labelled symmetric precubical sets to cubical transition systems is not a left Quillen functor. It is only a left adjoint (Proposition 7.5). An intermediate model category must be used in the proofs to get the Quillen equivalences (Theorem 7.10). The cause of this problem is the family of cofibrations consisting of the inclusions $\partial\square_S[x,y] \subset \square_S[x,y]$ of the boundary of a labelled 2-cube to the full 2-cube (Proposition 7.5) for x and y running over the set of labels Σ. The same inclusion prevents the segment object of labelled symmetric precubical sets from being very good. It is only good (Proposition 6.6 and the remark after the proof). The same family of cofibrations also prevents the segment object of cubical transition systems from being very good as well with respect to the augmented set of generating cofibrations (Theorem 7.10). As a consequence, the Olschok construction cannot tell us anything about the left determinedness of the model category of labelled symmetric precubical sets and about the augmented model category of cubical transition systems. The root of these phenomena is that the realization as cubical transition system of the boundary of a labelled 2-cube $\partial\square_S[x,y]$ is not equal to the boundary of the labelled 2-cube viewed as a cubical transition system. Indeed, the boundary of the cubical transition system $\partial C_2[x,y]$ *is not a colimit of cubes*, and so it cannot be the realization of a labelled symmetric precubical set. It is obtained by identifying states in the cubical transition system $\uparrow x\uparrow \sqcup \uparrow y\uparrow$ and $\uparrow x\uparrow$ (Definition 3.5) is not a colimit of cubes by [Gau11, Theorem 3.11]. The problem disappears in higher dimension because for all $n \geqslant 3$,

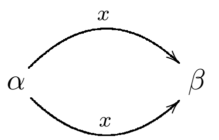

FIGURE 1. $\mathrm{Cyl}(\square_S[x])$: the cylinder of $\square_S[x]$ is homotopy equivalent to the 1-cube $\square_S[x]$.

the boundary of a labelled n-cube viewed as a cubical transition system $\partial C_n[x_1, \dots, x_n]$ is a colimit of cubes.

This new model category structure on labelled symmetric precubical sets is very different from the ones coming from algebraic topology. Indeed, the class of cofibrations is strictly larger than the class of monomorphisms. This makes impossible to use tools like Cisinski's homotopy theory of toposes [Cis02] or Hirschhorn's theory of Bousfield localization [Hir03]. The main technical tool of this paper is Marc Olschok's PhD [Ols09b] [Ols09a] instead. Moreover, not only the 1-cube is not weakly equivalent to a point; but also it is weakly equivalent to two copies of itself where the two initial (final resp.) states are identified as in Figure 1. This new model category is adapted, like the ones constructed on cubical transition systems in [Gau11], to the study of bisimulation [WN95] [JNW96]. In the case of Figure 1, the labelled symmetric precubical set has the same behavior as the 1-cube $\square_S[x]$ labelled by x. Indeed, the unique map from $\mathrm{Cyl}(\square_S[x])$ to $C_1[x]$ is a bisimulation.

Outline of the paper. Section 2 is a reminder about the Olschok construction of combinatorial model categories, at least the first part of his PhD devoted to the generalization of Cisinski's work. Only what is used in this paper is recalled. So the statement of Theorem 2.5 is certainly less general than what is written in [Ols09a] and [Ols09b]. Section 3 is a reminder about weak HDTS and cubical transition systems. Several important basic examples of such objects are given. Section 4 recalls the homotopy theory of cubical transition systems. The exposition is improved, so it is more than just a reminder. In particular, an explicit set of generating cofibrations is given. Section 5 recalls the definition of labelled symmetric precubical set. Once again, several important basic examples are given. Section 6 constructs the new model category structure on labelled symmetric precubical sets (Theorem 6.8). Roughly speaking, we *really* just have to mimic the construction of the model category structure on cubical transition systems. Section 7 recalls the construction of the realization functor from labelled symmetric precubical sets to cubical transition systems. The exposition is much better than in [Gau10b] where it is introduced, so it is also more than just a reminder. It is also proved in the same section that the realization functor is not a left Quillen functor, and it is explained how to overcome this problem by adding one generating cofibration to the category of cubical transition systems. And Section 8 proves one of the main result of this paper: there exists a model category of labelled symmetric precubical sets which is Quillen equivalent to the homotopy theory of cubical transition systems (Theorem 8.9). The last section restricts the homotopy constructions to the full reflective subcategory of labelled symmetric precubical sets satisfying the HDA paradigm (Theorem 9.5) and proves a similar result (Theorem 9.6).

Prerequisites. The necessary bibliographical references and reminders are given throughout the text. The category of sets is denoted by **Set**. All categories are locally small. The set of maps in a category $\mathcal{K}$ from X to Y is denoted by $\mathcal{K}(X, Y)$. The locally small category those objects are the maps of $\mathcal{K}$ and those morphisms are the commutative squares is denoted by $\mathrm{Mor}(\mathcal{K})$. The initial (final resp.) object, if it exists, is always denoted by $\varnothing$ ($\mathbf{1}$). The identity of an object X is denoted by Id_X. A subcategory is always *isomorphism-closed*. We refer to [AR94] for locally presentable categories, to [Ros09] for combinatorial model categories, and to [AHS06] for topological categories (i.e. categories equipped with a topological functor towards a power of the category of sets). We refer to [Hov99] and to [Hir03] for model categories. For general facts about weak factorization systems, see also [KR05]. We recommend the reading of Marc Olschok's PhD [Ols09b]. The first part, published in [Ols09a], is used in this paper.

2. The Olschok construction of model categories

We want to review the Olschok construction of combinatorial model categories [Ols09a], as it already is used in [Gau11], and as it is used in this paper, i.e. by starting from a *good segment object*.

Let f and g be two maps of a locally presentable category $\mathcal{K}$. Denote by $f\square g$ when f satisfies the *left lifting property* with respect to g (or equivalently g satisfies the *right lifting property* with respect to f). Let us introduce the notations $\mathbf{inj}_{\mathcal{K}}(\mathcal{C}) = \{g \in \mathcal{K}, \forall f \in \mathcal{C}, f\square g\}$, $\mathbf{proj}_{\mathcal{K}} = \{f \in \mathcal{K}, \forall g \in \mathcal{C}, f\square g\}$ and $\mathbf{cof}_{\mathcal{K}}(\mathcal{C}) = \mathbf{proj}_{\mathcal{K}}(\mathbf{inj}_{\mathcal{K}}(\mathcal{C}))$ where $\mathcal{C}$ is a class of maps of a locally presentable category $\mathcal{K}$. The class of morphisms of $\mathcal{K}$ that are transfinite compositions of pushouts of elements of $\mathcal{C}$ is denoted by $\mathbf{cell}_{\mathcal{K}}(\mathcal{C})$.

The main tool in the Olschok construction of model categories [Ols09a] is the notion of *good cylinder*. We want to explain here the particular case where the good cylinder is obtained by taking the binary product with a good segment object.

2.1. **Notation.** *For every map $f : X \to Y$ and every natural transformation $\alpha : F \to F'$ between two endofunctors of $\mathcal{K}$, the map $f \star \alpha$ is the canonical map*

$$f \star \alpha : FY \sqcup_{FX} F'X \longrightarrow F'Y$$

induced by the commutative diagram of solid arrows

$$\begin{tikzcd} FX \arrow[r, "\alpha_X"] \arrow[d, "Ff"'] & F'X \arrow[d, "F'f"] \\ FY \arrow[r, "\alpha_Y"] & F'Y \end{tikzcd}$$

and the universal property of the pushout.

2.2. **Definition.** *Let I be a set of maps of a locally presentable category $\mathcal{K}$. A* good segment object *with respect to I is an object V of $\mathcal{K}$ together with two maps $\gamma^k : \mathbf{1} \to V$ for $k = 0, 1$ ($\sigma : V \to \mathbf{1}$ will denote the canonical map towards the terminal object) such that the codiagonal $\mathbf{1} \sqcup \mathbf{1} \to \mathbf{1}$ factors as a composite*

$$\mathbf{1} \sqcup \mathbf{1} \xrightarrow{\gamma^0 \sqcup \gamma^1} V \xrightarrow{\sigma} \mathbf{1}$$

and such that the left-hand map $\gamma^0 \sqcup \gamma^1$ induces for all $X \in \mathcal{K}$ a map

$$X \sqcup X \xrightarrow{\gamma^0_X \sqcup \gamma^1_X} V \times X \in \mathbf{cof}_{\mathcal{K}}(I).$$

When moreover the right-hand map σ *belongs to* $\mathbf{inj}_{\mathcal{K}}(I)$*,* V *is called a* very good segment object*.*

2.3. **Definition.** *Let* I *be a set of maps of a locally presentable category. A good segment object* V *with respect to* I *is* cartesian *if it is exponential (the right adjoint of* $V \times -$ *will be denoted by* $(-)^V$*) and if there are the inclusions* $\mathbf{cof}_{\mathcal{K}}(I) \star \gamma \subset \mathbf{cof}_{\mathcal{K}}(I)$ *and* $\mathbf{cof}_{\mathcal{K}}(I) \star \gamma^k \subset \mathbf{cof}_{\mathcal{K}}(I)$ *for* $k = 0, 1$ *where* γ *and* γ^k *for* $k = 0, 1$ *are the natural transformations*

$$\gamma : (\mathbf{1} \times -) \sqcup (\mathbf{1} \times -) \xrightarrow{\gamma} (V \times -)$$

and

$$\gamma^k : (\mathbf{1} \times -) \xrightarrow{\iota^k} (\mathbf{1} \times -) \sqcup (\mathbf{1} \times -) \longrightarrow (V \times -).$$

2.4. **Notation.** *Let* I *and* S *be two sets of maps of a locally presentable category* $\mathcal{K}$*. Let* V *be a good segment object with respect to* I*. Denote by* $\Lambda_{\mathcal{K}}(V, S, I)$ *the set of maps:*

- $\Lambda^0_{\mathcal{K}}(V, S, I) = S \cup (I \star \gamma^0) \cup (I \star \gamma^1)$
- $\Lambda^{n+1}_{\mathcal{K}}(V, S, I) = \Lambda^n_{\mathcal{K}}(V, S, I) \star \gamma$
- $\Lambda_{\mathcal{K}}(V, S, I) = \bigcup_{n \geqslant 0} \Lambda^n_{\mathcal{K}}(V, S, I)$.

Let us denote by $\mathcal{W}_{\mathcal{K}}(V, S, I)$ the class of maps defined as follows. A map $f : X \to Y$ of $\mathcal{K}$ belongs to $\mathcal{W}_{\mathcal{K}}(V, S, I)$ if and only if for every object T which is $\Lambda_{\mathcal{K}}(V, S, I)$-injective, the induced set map

$$\mathcal{K}(Y, T)/{\simeq} \xrightarrow{\cong} \mathcal{K}(X, T)/{\simeq}$$

is a bijection where $\simeq$ means the homotopy relation associated with the cylinder $\mathrm{Cyl}(-) = V \times -$, i.e. for all maps $f, g : X \to Y$, $f \simeq g$ is equivalent to the existence of $H : \mathrm{Cyl}(X) \to Y$ with $H \circ \gamma^0 = f$ and $H \circ \gamma^1 = g$.

We are now ready to recall the Olschok construction for this particular setting:

2.5. **Theorem.** *(Olschok) Let* $\mathcal{K}$ *be a locally presentable category. Let* I *be a set of maps of* $\mathcal{K}$*. Let* $S \subset \mathbf{cof}_{\mathcal{K}}(I)$ *be an arbitrary set of maps of* $\mathcal{K}$*. Let* V *be a good cartesian segment object with respect to* I*. Suppose also that for any object* X *of* $\mathcal{K}$*, the canonical map* $\varnothing \to X$ *belongs to* $\mathbf{cof}_{\mathcal{K}}(I)$*. Then there exists a unique combinatorial model category structure with class of cofibrations* $\mathbf{cof}_{\mathcal{K}}(I)$ *such that the fibrant objects are the* $\Lambda_{\mathcal{K}}(V, S, I)$*-injective objects. The class of weak equivalences is* $\mathcal{W}_{\mathcal{K}}(V, S, I)$*. All objects are cofibrant. Moreover, if* V *is very good, then the hypothesis* $S \subset \mathbf{cof}_{\mathcal{K}}(I)$ *can be removed and* $\mathcal{W}_{\mathcal{K}}(V, S, I)$ *is the localizer generated by* S *(with respect to the class of cofibrations* $\mathbf{cof}_{\mathcal{K}}(I)$*).*

Proof. Since all objects are cofibrant, the class of weak equivalences is necessarily $\mathcal{W}_{\mathcal{K}}(V, S, I)$ by [Hir03, Theorem 7.8.6] ($\mathcal{K}(X, T)/{\simeq}$ ($\mathcal{K}(Y, T)/{\simeq}$ resp.) is the set of morphisms in the homotopy category from X (Y resp.) to T and the Yoneda lemma can be used). Hence the uniqueness. The existence is a consequence of [Ols09a, Theorem 3.16]. The last assertion is a consequence of [Ols09a, Theorem 4.5]. □

2.6. **Notation.** *For* $S = \varnothing$*, the model category is just denoted by* $\mathcal{K}$*.*

If the segment is very good in Theorem 2.5, then $\mathcal{K}$ is left determined in the sense of [RT03]. And the model category we obtain for $S \neq \varnothing$ is the Bousfield localization $\underline{\mathbf{L}}_{\mathcal{S}}(\mathcal{K})$ of the left determined one by the set of maps S. If the segment is only good, then the Olschok construction can only tell us that the model category we obtained is the Bousfield localization

$\underline{\mathbf{L}}_{\Lambda_{\mathcal{K}}(V,S,I)}(\mathcal{K})$ [1] with respect to $\Lambda_{\mathcal{K}}(V,S,I)$ because, by [Ols09a, Lemma 4.4], the class of maps $\mathcal{W}_{\mathcal{K}}(V,S,I)$ is the localizer generated by $\Lambda_{\mathcal{K}}(V,S,I)$: this point is important in the proof of Proposition 8.4.

3. About cubical transition systems

3.1. **Notation.** *A non empty set of* labels Σ *is fixed.*

3.2. **Definition.** *A* weak higher dimensional transition system (weak HDTS) *consists of a triple*

$$(S, \mu : L \to \Sigma, T = \bigcup_{n\geqslant 1} T_n)$$

where S *is a set of* states*, where* L *is a set of* actions*, where* $\mu : L \to \Sigma$ *is a set map called the* labelling map*, and finally where* $T_n \subset S \times L^n \times S$ *for* $n \geqslant 1$ *is a set of* n-transitions *or* n-dimensional transitions *such that one has:*

- *(Multiset axiom) For every permutation* σ *of* $\{1,\dots,n\}$ *with* $n \geqslant 2$*, if* $(\alpha,u_1,\dots,u_n,\beta)$ *is a transition, then* $(\alpha,u_{\sigma(1)},\dots,u_{\sigma(n)},\beta)$ *is a transition as well.*
- *(Composition axiom) For every* $(n+2)$*-tuple* $(\alpha,u_1,\dots,u_n,\beta)$ *with* $n \geqslant 3$*, for every* $p,q \geqslant 1$ *with* $p+q<n$*, if the five tuples* $(\alpha,u_1,\dots,u_n,\beta)$*,* $(\alpha,u_1,\dots,u_p,\nu_1)$*,* $(\nu_1,u_{p+1},\dots,u_n,\beta)$*,* $(\alpha,u_1,\dots,u_{p+q},\nu_2)$ *and* $(\nu_2,u_{p+q+1},\dots,u_n,\beta)$ *are transitions, then the* $(q+2)$*-tuple* $(\nu_1,u_{p+1},\dots,u_{p+q},\nu_2)$ *is a transition as well.*

A map of weak higher dimensional transition systems

$$f : (S, \mu : L \to \Sigma, (T_n)_{n\geqslant 1}) \to (S', \mu' : L' \to \Sigma, (T'_n)_{n\geqslant 1})$$

consists of a set map $f_0 : S \to S'$*, a commutative square*

$$\begin{tikzcd} L \arrow[r, "\mu"] \arrow[d, "\widetilde{f}"'] & \Sigma \arrow[d, equal] \\ L' \arrow[r, "\mu'"'] & \Sigma \end{tikzcd}$$

such that if $(\alpha,u_1,\dots,u_n,\beta)$ *is a transition, then* $(f_0(\alpha),\widetilde{f}(u_1),\dots,\widetilde{f}(u_n),f_0(\beta))$ *is a transition. The corresponding category is denoted by* **WHDTS***. The* n*-transition* $(\alpha,u_1,\dots,u_n,\beta)$ *is also called a* transition from α to β*.*

3.3. **Notation.** *The labelling map from the set of actions to the set of labels will be very often denoted by* μ*.*

The category **WHDTS** is locally finitely presentable by [Gau10b, Theorem 3.4]. The functor

$$\omega : \mathbf{WHDTS} \longrightarrow \mathbf{Set}^{\{s\}\cup\Sigma}$$

taking the weak higher dimensional transition system $(S, \mu : L \to \Sigma, (T_n)_{n\geqslant 1})$ to the $(\{s\}\cup\Sigma)$-tuple of sets $(S, (\mu^{-1}(x))_{x\in\Sigma}) \in \mathbf{Set}^{\{s\}\cup\Sigma}$ is topological by [Gau10b, Theorem 3.4] too.

There is a slight change in the terminology with respect to the one of [Gau10b] and [Gau11]. The *Coherence axiom* is called now the *Composition axiom* because this axiom really looks like a 5-ary composition even if it is not known what conclusion should be drawn from such an observation.

---

[1] The Bousfield localization of a left proper combinatorial model category with respect to any *set* of maps always exists and is left proper combinatorial [Ros09] [Lur09] [Hir03, Theorem 3.3.19].

3.4. **Notation.** *For $n \geqslant 1$, let $0_n = (0, \dots, 0)$ (n-times) and $1_n = (1, \dots, 1)$ (n-times). By convention, let $0_0 = 1_0 = ()$.*

We give now some important examples of weak HDTS. In each of the following examples, the Multiset axiom and the Composition axiom are satisfied for trivial reasons.

1. Let $n \geqslant 0$. Let $x_1, \dots, x_n \in \Sigma$. The *pure n-transition* $C_n[x_1, \dots, x_n]^{ext}$ is the weak HDTS with the set of states $\{0_n, 1_n\}$, with the set of actions $\{(x_1, 1), \dots, (x_n, n)\}$ and with the transitions all $(n+2)$-tuples $(0_n, (x_{\sigma(1)}, \sigma(1)), \dots, (x_{\sigma(n)}, \sigma(n)), 1_n)$ for σ running over the set of permutations of the set $\{1, \dots, n\}$.
2. Every set X may be identified with the weak HDTS having the set of states X, with no actions and no transitions.
3. For every $x \in \Sigma$, let us denote by $\underline{x}$ the weak HDTS with no states, one action x, and no transitions. Warning: the weak HDTS $\{x\}$ contains one state x and no actions whereas the weak HDTS $\underline{x}$ contains no states and one action x.

The following example plays a special role in the theory:

3.5. **Notation.** *For every $x \in \Sigma$, let us denote by $\uparrow x \uparrow$ the weak HDTS with four states $\{1, 2, 3, 4\}$, one action x and two transitions $(1, x, 2)$ and $(3, x, 4)$.*

Another important example is the one of the n-cube which is recalled now.

3.6. **Proposition.** [Gau10b, Proposition 5.2] *Let $n \geqslant 0$ and $x_1, \dots, x_n \in \Sigma$. Let $T_d \subset \{0,1\}^n \times \{(x_1, 1), \dots, (x_n, n)\}^d \times \{0,1\}^n$ (with $d \geqslant 1$) be the subset of $(d+2)$-tuples*

$$((\epsilon_1, \dots, \epsilon_n), (x_{i_1}, i_1), \dots, (x_{i_d}, i_d), (\epsilon'_1, \dots, \epsilon'_n))$$

such that

- *$i_m = i_n$ implies $m = n$, i.e. there are no repetitions in the list $(x_{i_1}, i_1), \dots, (x_{i_d}, i_d)$*
- *for all i, $\epsilon_i \leqslant \epsilon'_i$*
- *$\epsilon_i \neq \epsilon'_i$ if and only if $i \in \{i_1, \dots, i_d\}$.*

Let $\mu : \{(x_1, 1), \dots, (x_n, n)\} \to \Sigma$ be the set map defined by $\mu(x_i, i) = x_i$. Then

$$C_n[x_1, \dots, x_n] = (\{0,1\}^n, \mu : \{(x_1, 1), \dots, (x_n, n)\} \to \Sigma, (T_d)_{d \geqslant 1})$$

is a well-defined weak HDTS called the n-cube.

For $n = 0$, $C_0[]$, also denoted by C_0, is nothing else but the weak HDTS $(\{()\}, \mu : \varnothing \to \Sigma, \varnothing)$. For every $x \in \Sigma$, one has $C_1[x] = C_1[x]^{ext}$.

3.7. **Definition.** *Let $n \geqslant 1$ and $x_1, \dots, x_n \in \Sigma$. Let $\partial C_n[x_1, \dots, x_n]$ be the weak HDTS defined by removing from its set of transitions all n-transitions. It is called the* boundary *of $C_n[x_1, \dots, x_n]$.*

We restricted our attention in [Gau11] to the so-called cubical transition systems, i.e. the weak HDTS which are equal to the union of their subcubes and which contain all useful examples.

3.8. **Definition.** *Let X be a weak HDTS. A* cube *of X is a map $C_n[x_1, \dots, x_n] \longrightarrow X$. A* subcube *of X is the image of a cube of X. A weak HDTS is a* cubical transition system *if it is equal to the union of its subcubes. The full subcategory of cubical transition systems is denoted by* **CTS**.

Note that the weak HDTS $\partial C_2[x_1,x_2]$ is not a colimit of cubes but is cubical: it is obtained by identifying states in the cubical transition system $\uparrow x_1\uparrow \sqcup \uparrow x_2\uparrow$. This is the reason why we do not work in [Gau11] with the subcategory of *colimits* of cubes.

The category **CTS** is a small-injectivity class, and a full *coreflective* locally finitely presentable subcategory of **WHDTS** by [Gau11, Corollary 3.15]. More precisely, a weak HDTS is cubical if and only if it is injective with respect to the maps $\underline{x} \subset C_1[x]$ for all $x \in \Sigma$ and to the maps $C_n[x_1,\dots,x_n]^{ext} \subset C_n[x_1,\dots,x_n]$ for all $n \geqslant 0$ and $x_1,\dots,x_n \in \Sigma$ by [Gau11, Theorem 3.6].

3.9. **Definition.** *Let X be a weak HDTS. An action u of X is* used *if there exists a* 1*-transition* (α,u,β)*.* All actions are used *if X is injective with respect to the maps $\underline{x} \subset C_1[x]$ for all $x \in \Sigma$.*

3.10. **Definition.** *A weak HDTS X satisfies the* Intermediate state axiom *if for every $n \geqslant 2$, every p with $1 \leqslant p < n$ and every transition $(\alpha,u_1,\dots,u_n,\beta)$ of X, there exists a (not necessarily unique) state ν such that both $(\alpha,u_1,\dots,u_p,\nu)$ and $(\nu,u_{p+1},\dots,u_n,\beta)$ are transitions.*

By [Gau11, Proposition 6.6], a weak HDTS satisfies the Intermediate state axiom if and only if it is injective with respect to the maps $C_n[x_1,\dots,x_n]^{ext} \subset C_n[x_1,\dots,x_n]$ for all $n \geqslant 0$ and $x_1,\dots,x_n \in \Sigma$. So a weak HDTS is cubical if and only if all actions are used and it satisfies the Intermediate state axiom.

4. The homotopy theory of cubical transition systems

Let us recall now the homotopy theory of **CTS**. This third paper about higher dimensional transition systems contains some improvements in the exposition of this theory. In particular, a set of generating cofibrations can now be exhibited (in [Gau11], the existence of a set of generating cofibrations is proved using transfinite techniques).

4.1. **Definition.** *A* cofibration *of cubical transition systems is a map of weak HDTS inducing an injection between the set of actions.*

To make the reading of this paper easier, let us introduce a new notation (which will be used later in Proposition 7.8 and Proposition 7.9).

4.2. **Proposition.** *Consider a set map $\mu : L \to \Sigma$. The weak HDTS $\mathbb{S}(\mu)$ with set of states $\{0\}$, with labelling map μ and with set of transitions $\{0\} \times \bigcup_{n\geqslant 1} L^n \times \{0\}$ is cubical. The mapping $\mathbb{S}$ yields a well-defined functor from* **Set**$\downarrow\Sigma$ *to* **CTS***.*

Proof. All actions are used and $\mathbb{S}(\mu)$ satisfies the Intermediate state axiom. □

4.3. **Definition.** *Let us call $V := \mathbb{S}(\Sigma \times \{0,1\} \to \Sigma)$ the* segment object *of* **CTS** *where $\Sigma \times \{0,1\} \to \Sigma$ is the projection map.*

Note that $\mathbb{S}(\mathrm{Id}_\Sigma)$ is the terminal object $\mathbf{1}$ of **CTS**. For $k \in \{0,1\}$, denote by $\gamma^k : \mathbf{1} \to V$ the map of cubical transition systems induced by the composite set map $\Sigma \cong \Sigma \times \{k\} \subset \Sigma \times \{0,1\}$. And denote by $\sigma : V \to \mathbf{1}$ the canonical map, also induced by the projection map $\Sigma \times \{0,1\} \to \Sigma$. Let $\gamma = \gamma^0 \sqcup \gamma^1 : \mathbf{1} \sqcup \mathbf{1} \to V$.

The segment V is exponential by [Gau11, Proposition 5.8]. It is very good by [Gau11, Proposition 5.7] and cartesian by [Gau11, Proposition 5.10]. We are going to use the following fact which is already implicitly present in [Gau10b] and [Gau11].

4.4. **Proposition.** *Let $f : A \to B$ be a map of weak HDTS which is bijective on states and actions. Then it is injective on transitions.*

Proof. Let $(\alpha, u_1, \dots, u_m, \beta)$ and $(\alpha', u'_1, \dots, u'_{m'}, \beta')$ be two transitions of A such that

$$(f_0(\alpha), \widetilde{f}(u_1), \dots, \widetilde{f}(u_m), f_0(\beta)) = (f_0(\alpha'), \widetilde{f}(u'_1), \dots, \widetilde{f}(u'_{m'}), f_0(\beta')).$$

Then $m = m'$, $f_0(\alpha) = f_0(\alpha')$, $\widetilde{f}(u_i) = \widetilde{f}(u'_i)$ for $1 \leqslant i \leqslant n$ and $f_0(\beta) = f_0(\beta')$. So by hypothesis, $\alpha = \alpha'$, $\beta = \beta'$ and $u_i = u'_i$ for $1 \leqslant i \leqslant n$. Hence

$$(\alpha, u_1, \dots, u_m, \beta) = (\alpha', u'_1, \dots, u'_{m'}, \beta').$$

$\square$

4.5. **Notation.** *Denote by $\mathcal{I}$*[2] *the set of maps of cubical transition systems:*

$$\begin{aligned} \mathcal{I} = \{C : \varnothing \to \{0\}, R : \{0,1\} \to \{0\}\} \\ \cup \{\partial C_n[x_1, \dots, x_n] \to C_n[x_1, \dots, x_n] \mid n \geqslant 1 \text{ and } x_1, \dots, x_n \in \Sigma\} \\ \cup \{C_1[x] \to \uparrow x \uparrow \mid x \in \Sigma\} \end{aligned}$$

4.6. **Theorem.** *The class of cofibrations of cubical transition systems is equal to*

$$\mathbf{cell}_{\mathbf{CTS}}(\mathcal{I}) = \mathbf{cof}_{\mathbf{CTS}}(\mathcal{I}).$$

Proof. Let $f : A \to B$ be a cofibration of cubical transition systems, i.e. a map of cubical transition systems which is injective on actions. Let us factor f as a composite $A \to Z \to B$ where the left-hand map belongs to $\mathbf{cell}_{\mathbf{CTS}}(\{C, R\})$ and where the right-hand map belongs to $\mathbf{inj}_{\mathbf{CTS}}(\{C, R\})$. Then the sets of states of Z and B coincide, therefore we can suppose without lack of generality that f induces a bijection between the sets of states. For every action u of B which does not belong to A, the map $\underline{u} \to B$ factors (not in a unique way) as a composite $\underline{\mu(u)} \to C_1[\mu(u)] \to B$ because B is cubical. The map $f : A \to B$ is bijective on states, therefore the composite $C_0 \sqcup C_0 \cong \partial C_1[\mu(u)] \subset C_1[\mu(u)] \to B$ factors as a composite $C_0 \sqcup C_0 \to A \to B$. Then for every action u of B not in A, there exists a commutative square

$$\begin{tikzcd} C_0 \sqcup C_0 \cong \partial C_1[\mu(u)] \arrow[r, "g_u"] \arrow[d, "f_u"'] & A \arrow[d] \\ C_1[\mu(u)] \arrow[r] & B. \end{tikzcd}$$

Then consider the pushout diagram

$$\begin{tikzcd} \bigsqcup_u \partial C_1[\mu(u)] \arrow[r, "g_u"] \arrow[d, "f_u"'] & A \arrow[d] \\ \bigsqcup_u C_1[\mu(u)] \arrow[r] & Z. \arrow[ul, phantom, "\ulcorner", very near start] \end{tikzcd}$$

---

[2] The notations $C : \varnothing \to \{0\}$ and $R : \{0,1\} \to \{0\}$ are already used in [Gau03] and in [Gau09] for the same generating cofibrations (in different categories of course). We will stick to this notation here, and for the model category of labelled symmetric precubical sets as well.

The canonical map $Z \to B$ induced by the pushout is bijective both on states and on actions, and by Proposition 4.4, injective on transitions. Let us now factor the map $Z \to B$ as a composite $Z \to D \to B$ where the left-hand map belongs to

$$\begin{aligned}\mathbf{cell_{CTS}}(\{\partial C_n[x_1,\dots,x_n] \to C_n[x_1,\dots,x_n] \mid n \geqslant 2 \text{ and } x_1,\dots,x_n \in \Sigma\}\\ \cup \{C_0 \sqcup C_0 \sqcup C_1[x] \to \uparrow\! x \!\uparrow \mid x \in \Sigma\})\end{aligned}$$

and the right-hand map belongs to

$$\begin{aligned}\mathbf{inj_{CTS}}(\{\partial C_n[x_1,\dots,x_n] \to C_n[x_1,\dots,x_n] \mid n \geqslant 2 \text{ and } x_1,\dots,x_n \in \Sigma\}\\ \cup \{C_0 \sqcup C_0 \sqcup C_1[x] \to \uparrow\! x \!\uparrow \mid x \in \Sigma\}).\end{aligned}$$

where the map $C_0 \sqcup C_0 \sqcup C_1[x] \to \uparrow x \uparrow$ is defined so that it is bijective on states. It is important to notice that the maps $\partial C_n[x_1,\dots,x_n] \to C_n[x_1,\dots,x_n]$ for every $n \geqslant 2$ and every $x_1,\dots,x_n \in \Sigma$ and the maps $C_0 \sqcup C_0 \sqcup C_1[x] \to \uparrow\! x \!\uparrow$ for every $x \in \Sigma$ are bijective on states and actions. Therefore the two maps of cubical transition systems $Z \to D$ and $D \to B$ are bijective on states and actions, and by Proposition 4.4 injective on transitions.

Let (α, u, β) be a 1-transition of B. Then u is an action of B and therefore of D as well and α and β are two states of D. Since D is cubical, there exists a 1-transition (α', u, β') of D giving rise to a map $C_1[\mu(u)] \to D$. Then consider the commutative diagram

$$\begin{tikzcd}
\{\alpha\} \sqcup \{\beta\} \sqcup C_1[\mu(u)] \arrow[r] \arrow[d] & D \arrow[d] \\
\uparrow\!\mu(u)\!\uparrow \arrow[r] \arrow[ur, dashed, "k"] & B.
\end{tikzcd}$$

The existence of the lift k implies that the transition (α, u, β) belongs to D, hence the map $D \to B$ is surjective on 1-transitions. Let us prove by induction on $n \geqslant 1$ that the map $D \to B$ is surjective on p-transitions for $p \leqslant n$.

Let $(\alpha, u_1, \dots, u_{n+1}, \beta)$ be a $(n+1)$-transition of B, giving rise to a map

$$C_{n+1}^{ext}[\mu(u_1), \dots, \mu(u_{n+1})] \longrightarrow B,$$

which factors as a composite $C_{n+1}^{ext}[\mu(u_1), \dots, \mu(u_{n+1})] \to C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \to B$ because B is cubical. The composite $\partial C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \subset C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \to B$ factors uniquely as a composite $\partial C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \to D \to B$ by the induction hypothesis. We obtain a commutative diagram of cubical transition systems

$$\begin{tikzcd}
\partial C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \arrow[r] \arrow[d] & D \arrow[d] \\
C_{n+1}[\mu(u_1), \dots, \mu(u_{n+1})] \arrow[r] \arrow[ur, dashed, "k"] & B.
\end{tikzcd}$$

The existence of the lift k implies that the transition $(\alpha, u_1, \dots, u_{n+1}, \beta)$ belongs to D, hence the map $D \to B$ is surjective on $(n+1)$-transitions. So we obtain $D \cong B$.

The map $C_0 \sqcup C_0 \sqcup C_1[x] \to \uparrow x\uparrow$ is the composite $C_0 \sqcup C_0 \sqcup C_1[x] \to C_0 \sqcup C_0 \sqcup \uparrow x\uparrow \to \uparrow x\uparrow$ where the left-hand map is a pushout of the generating cofibration $C_1[x] \to \uparrow x\uparrow$ and where the right-hand map is a pushout of the generating cofibration $R : \{0,1\} \to \{0\}$ twice. So $\mathbf{cell}_{\mathbf{CTS}}(\mathcal{I})$ is the class of cofibrations. Therefore $\mathbf{cell}_{\mathbf{CTS}}(\mathcal{I})$ is closed under retract and $\mathbf{cell}_{\mathbf{CTS}}(\mathcal{I}) = \mathbf{cof}_{\mathbf{CTS}}(\mathcal{I})$. ☐

4.7. **Corollary.** *Let S be an arbitrary set of maps. There exists a unique combinatorial model category structure on* $\mathbf{CTS}$ *such that $\mathcal{I}$ is the set of generating cofibrations and such that the fibrant objects are the $\Lambda_{\mathbf{CTS}}(V, S, \mathcal{I})$-injective objects. All objects are cofibrant. The class of weak equivalences is the localizer generated by S.*

Proof. This corollary is a consequence of Theorem 4.6 and Theorem 2.5. ☐

5. About labelled symmetric precubical sets

Let $[0] = \{()\}$ and $[n] = \{0,1\}^n$ for $n \geqslant 1$. By convention, one has $\{0,1\}^0 = [0] = \{()\}$. The set $[n]$ is equipped with the product ordering $\{0 < 1\}^n$. Let $\delta_i^\alpha : [n-1] \to [n]$ be the set map defined for $1 \leqslant i \leqslant n$ and $\alpha \in \{0,1\}$ by $\delta_i^\alpha(\epsilon_1, \dots, \epsilon_{n-1}) = (\epsilon_1, \dots, \epsilon_{i-1}, \alpha, \epsilon_i, \dots, \epsilon_{n-1})$. These maps are called the *face maps*. Let $\sigma_i : [n] \to [n]$ be the set map defined for $1 \leqslant i \leqslant n-1$ and $n \geqslant 2$ by $\sigma_i(\epsilon_1, \dots, \epsilon_n) = (\epsilon_1, \dots, \epsilon_{i-1}, \epsilon_{i+1}, \epsilon_i, \epsilon_{i+2}, \dots, \epsilon_n)$. These maps are called the *symmetry maps*. The subcategory of **Set** generated by the composites of face maps and symmetry maps is denoted by $\square_S$.

5.1. **Definition.** [GM03] *A* symmetric precubical set *is a presheaf over $\square_S$. The corresponding category is denoted by $\square_S^{op}\mathbf{Set}$. If K is a symmetric precubical set, then let $K_n := K([n])$ and for every set map $f : [m] \to [n]$ of $\square_S$, denote by $f^* : K_n \to K_m$ the corresponding set map.*

Let $\square_S[n] := \square_S(-, [n])$. It is called the *$n$-dimensional (symmetric) cube*. By the Yoneda lemma, one has the natural bijection of sets $\square_S^{op}\mathbf{Set}(\square_S[n], K) \cong K_n$ for every precubical set K. The *boundary* of $\square_S[n]$ is the symmetric precubical set denoted by $\partial\square_S[n]$ defined by removing the interior of $\square_S[n]$: $(\partial\square_S[n])_k := (\square_S[n])_k$ for $k < n$ and $(\partial\square_S[n])_k = \varnothing$ for $k \geqslant n$. In particular, one has $\partial\square_S[0] = \varnothing$. An *$n$-dimensional* symmetric precubical set K is a symmetric precubical set such that $K_p = \varnothing$ for $p > n$ and $K_n \neq \varnothing$. The labelled at most n-dimensional symmetric precubical set $K_{\leqslant n}$ denotes the labelled symmetric precubical set defined by $(K_{\leqslant n})_p = K_p$ for $p \leqslant n$ and $(K_{\leqslant n})_p = \varnothing$ for $p > n$.

5.2. **Notation.** *Let $f : K \to L$ be a morphism of symmetric precubical sets. Let $n \geqslant 0$. The set map from K_n to L_n induced by f will be sometimes denoted by f_n.*

5.3. **Notation.** *Let $\partial_i^\alpha = (\delta_i^\alpha)^*$. And let $s_i = (\sigma_i)^*$.*

5.4. **Proposition.** *(*[Gau10a, Proposition A.4]*) The following data define a symmetric precubical set denoted by $!^S\Sigma$:*

- $(!^S\Sigma)_0 = \{()\}$ *(the empty word)*
- *for $n \geqslant 1$, $(!^S\Sigma)_n = \Sigma^n$*
- $\partial_i^0(a_1, \dots, a_n) = \partial_i^1(a_1, \dots, a_n) = (a_1, \dots, \widehat{a_i}, \dots, a_n)$ *where the notation $\widehat{a_i}$ means that a_i is removed.*
- $s_i(a_1, \dots, a_n) = (a_1, \dots, a_{i-1}, a_{i+1}, a_i, a_{i+2}, \dots, a_n)$ *for $1 \leqslant i \leqslant n$.*

The map $!^S : \mathbf{Set} \to \square_S^{op}\mathbf{Set}$ yields a well-defined functor from the category of sets to the category of symmetric precubical sets.

5.5. **Definition.** *A* labelled symmetric precubical set (over Σ) *is an object of the comma category* $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$. *That is, an object is a map of symmetric precubical sets* $\ell : K \to !^S\Sigma$ *and a morphism is a commutative diagram*

$$\begin{tikzcd} K \arrow[rr] \arrow[dr] & & L \arrow[dl] \\ & !^S\Sigma. & \end{tikzcd}$$

The map ℓ *is called the* labelling map. *The symmetric precubical set* K *is sometimes called the* underlying symmetric precubical set *of the labelled symmetric precubical set. A labelled symmetric precubical set* $K \to !^S\Sigma$ *will be denoted by* $(K//\Sigma)$. *And the set of* n*-cubes* K_n *will be also denoted* $(K//\Sigma)_n$.

The link between labelled symmetric precubical sets and process algebra is detailed in [Gau08] and in the appendix of [Gau10a].

5.6. **Notation.** *Let* $n \geqslant 1$. *Let* $a_1, \dots, a_n$ *be labels of* Σ. *Let us denote by* $\square_S[a_1, \dots, a_n] : \square_S[n] \to !^S\Sigma$ *the labelled symmetric precubical set corresponding by the Yoneda lemma to the* n*-cube* $(a_1, \dots, a_n)$. *And let us denote by* $\partial\square_S[a_1, \dots, a_n] : \partial\square_S[n] \to !^S\Sigma$ *the labelled symmetric precubical set defined as the composite*

$$\partial\square_S[a_1, \dots, a_n] : \partial\square_S[n] \subset \square_S[n] \xrightarrow{\square_S[a_1,\dots,a_n]} !^S\Sigma.$$

Every set can be identified with a sum of 0*-cubes* $C_0[]$ *(also denoted by* C_0*).*

Since colimits are calculated objectwise for presheaves, the n-cubes are finitely accessible. Since the set of cubes is a dense (and hence strong) generator, the category of labelled symmetric precubical sets is locally finitely presentable by [AR94, Theorem 1.20 and Proposition 1.57]. When the set of labels Σ is the singleton $\{\tau\}$, the category $\square_S^{op}\mathbf{Set}{\downarrow}!^S\{\tau\}$ is isomorphic to the category of (unlabelled) symmetric precubical sets because $!^S\{\tau\}$ is the terminal symmetric precubical set.

6. THE HOMOTOPY THEORY OF LABELLED SYMMETRIC PRECUBICAL SETS

6.1. **Definition.** *The* segment object *of* $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ *is the labelled symmetric precubical set* $(!^S(\Sigma \times \{0,1\})//\Sigma)$ *induced by the projection map* $\Sigma \times \{0,1\} \to \Sigma$. *Let*

$$\mathrm{Cyl}(K//\Sigma) = (!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma).$$

Note that $\mathrm{Id}_{!^S\Sigma} : (!^S\Sigma//\Sigma)$ is the terminal object $\mathbf{1}$ of $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$. For $k \in \{0,1\}$, denote by $\gamma^k : (!^S\Sigma//\Sigma) \to (!^S(\Sigma \times \{0,1\})//\Sigma)$ the map of labelled symmetric precubical sets induced by the composite set map $\Sigma \cong \Sigma \times \{k\} \subset \Sigma \times \{0,1\}$. And denote by $\sigma : (!^S(\Sigma \times \{0,1\})//\Sigma) \to (!^S\Sigma//\Sigma)$ the canonical map, also induced by the projection map $\Sigma \times \{0,1\} \to \Sigma$. Let $\gamma = \gamma^0 \sqcup \gamma^1 : (!^S\Sigma//\Sigma) \sqcup (!^S\Sigma//\Sigma) \to (!^S(\Sigma \times \{0,1\})//\Sigma)$.

If $(K//\Sigma)$ and $(L//\Sigma)$ are two labelled symmetric precubical sets, then their binary product in $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ is the labelled symmetric precubical set $(K \times_{!^S\Sigma} L//\Sigma)$.

6.2. **Proposition.** *The segment object* $(!^S(\Sigma \times \{0,1\})//\Sigma)$ *is exponential.*

Proof. Let $(K//\Sigma)$ be a labelled symmetric precubical set. Then $(K//\Sigma)_n = K_n \times_{\Sigma^n} (\Sigma \times \{0,1\})^n \cong K_n \times \{0,1\}^n$, i.e. $(!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma) \cong ((K_* \times \{0,1\}^*)//\Sigma)$ with an obvious definition of the face and symmetry maps. So the associated cylinder functor $(!^S(\Sigma \times$

$\{0,1\})//\Sigma) \times -$ is colimit-preserving because the category of sets is cartesian-closed and because colimits are calculated objectwise in the category $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$. Since $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ is well-copowered by [AR94, Theorem 1.58], the cylinder is a left adjoint by the dual of the Special Adjoint Functor Theorem [ML98]. Hence the segment object is exponential. $\square$

6.3. **Definition.** *A map of labelled symmetric precubical sets $f : (K//\Sigma) \longrightarrow (L//\Sigma)$ is a* cofibration *if for every $n \geqslant 1$, the set map $K_n \longrightarrow L_n$ is one-to-one.*

6.4. **Proposition.** *The set of cofibrations*

$$\mathcal{I} = \{\partial\square_S[a_1,\dots,a_n] \subset \square_S[a_1,\dots,a_n] \mid n \geqslant 1 \text{ and } a_1,\dots,a_n \in \Sigma\} \\ \cup \{C : \varnothing \to \{0\}, R : \{0,1\} \to \{0\}\}$$

generates the class of cofibrations, i.e. the class of cofibrations is exactly $\mathbf{cof}_{\square_S^{op}\mathbf{Set}\downarrow!^S\Sigma}(\mathcal{I})$. Moreover, one has $\mathbf{cell}_{\square_S^{op}\mathbf{Set}\downarrow!^S\Sigma}(\mathcal{I}) = \mathbf{cof}_{\square_S^{op}\mathbf{Set}\downarrow!^S\Sigma}(\mathcal{I})$.

Proof. This kind of proof is standard. Let $f : (K//\Sigma) \to (L//\Sigma)$ be a cofibration of labelled symmetric precubical sets. Let $\mathcal{I}_0 = \{C : \varnothing \to \{0\}, R : \{0,1\} \to \{0\}\}$, and for $n \geqslant 1$, let $\mathcal{I}_n = \{\partial\square_S[a_1,\dots,a_n] \subset \square_S[a_1,\dots,a_n] \mid a_1,\dots,a_n \in \Sigma\}$. Let $f = f_0$. Factor f_0 as a composite $(K//\Sigma) \to (K^1//\Sigma) \overset{f^1}{\to} (L//\Sigma)$ where the left-hand map belongs to $\mathbf{cell}_{\square_S^{op}\mathbf{Set}\downarrow!^S\Sigma}(\mathcal{I}_0)$ and where the right-hand map belongs to $\mathbf{inj}_{\square_S^{op}\mathbf{Set}\downarrow!^S\Sigma}(\mathcal{I}_0)$. Then f^1 is bijective on 0-cubes and by hypothesis is one-to-one on n-cubes with $n \geqslant 1$. Let us suppose $f^n : (K^n//\Sigma) \to (L//\Sigma)$ constructed for $n \geqslant 1$ and let us suppose that it is bijective on k-cubes for $k < n$ and one-to-one on k-cubes for $k \geqslant n$. Consider the pushout diagram of labelled symmetric precubical sets

$$\begin{tikzcd}
\bigsqcup \partial\square_S[a_1,\dots,a_n] \arrow[r] \arrow[d] & (K^n//\Sigma) \arrow[d] \\
\bigsqcup \square_S[a_1,\dots,a_n] \arrow[r] & (K^{n+1}//\Sigma) \arrow[ul, phantom, "\ulcorner", very near start]
\end{tikzcd}$$

where the sum is over all commutative squares of the form

$$\begin{tikzcd}
\partial\square_S[a_1,\dots,a_n] \arrow[r] \arrow[d] & (K^n//\Sigma) \arrow[d] \\
\square_S[a_1,\dots,a_n] \arrow[r] & (L//\Sigma).
\end{tikzcd}$$

Then the map $f^{n+1} : (K^{n+1}//\Sigma) \to (L//\Sigma)$ is bijective on k-cubes for $k < n+1$ and one-to-one on k-cubes for $k \geqslant n+1$. Hence $f = \varinjlim f_n$. $\square$

6.5. **Remark.** *We denote in the same way, i.e. by $\mathcal{I}$, the set of generating cofibrations of $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ and of* **CTS**. *The context will always enable the reader to avoid any confusion.*

6.6. **Proposition.** *The codiagonal $(!^S\Sigma//\Sigma) \sqcup (!^S\Sigma//\Sigma) \longrightarrow (!^S\Sigma//\Sigma)$ factors as a composite*

$$(!^S\Sigma//\Sigma) \sqcup (!^S\Sigma//\Sigma) \longrightarrow (!^S(\Sigma \times \{0,1\})//\Sigma) \longrightarrow (!^S\Sigma//\Sigma)$$

such that the left-hand map induces a cofibration $(K/\!/\Sigma) \sqcup (K/\!/\Sigma) \to \mathrm{Cyl}(K/\!/\Sigma)$ *for any labelled symmetric precubical set* $(K/\!/\Sigma)$*. In other terms, the segment object* $(!^S(\Sigma \times \{0,1\})/\!/\Sigma)$ *is good.*

Proof. The left-hand map is induced by the two inclusions $\Sigma \cong \Sigma \times \{\epsilon\} \subset \Sigma \times \{0,1\}$ with $\epsilon = 0, 1$. The right-hand map is induced by the projection $\Sigma \times \{0,1\} \longrightarrow \Sigma$. For $n \geqslant 1$, the left-hand map induces on the sets of n-cubes the one-to-one set map $(\Sigma \times \{0\})^n \sqcup (\Sigma \times \{1\})^n \subset (\Sigma \times \{0,1\})^n$. So for any labelled symmetric precubical set $(K/\!/\Sigma)$, and any $n \geqslant 1$, the map $(K/\!/\Sigma) \sqcup (K/\!/\Sigma) \to \mathrm{Cyl}(K/\!/\Sigma)$ induces on the sets of n-cubes the one-to-one set map

$$(K_n \times \{0\}^n) \sqcup (K_n \times \{1\}^n) \subset (K_n \times \{0,1\})^n.$$

Note that the set map $(!^S\Sigma \sqcup !^S\Sigma)_0 \longrightarrow (!^S(\Sigma \times \{0,1\}))_0$ is not one-to-one because it is isomorphic to the set map $R : \{0,1\} \to \{0\}$. □

The segment object $(!^S(\Sigma \times \{0,1\})/\!/\Sigma)$ is not very good. It is easy to prove that the right-hand map satisfies the right lifting property with respect to all generating cofibrations except the cofibrations $\partial\square_S[x,y] \to \square_S[x,y]$ for $x, y \in \Sigma$. Indeed, in the commutative square of solid arrows of labelled symmetric precubical sets

$$\begin{tikzcd}
\partial\square_S[x,y] \arrow[r, "g"] \arrow[d, "f"'] & !^S(\Sigma \times \{0,1\}) \arrow[d] \\
\square_S[x,y] \arrow[r] \arrow[ur, dashed, "k"] & !^S\Sigma
\end{tikzcd}$$

the lift k exists if and only if two opposite faces of $\partial\square_S[x,y]$ are labelled by g in $!^S(\Sigma \times \{0,1\})$ by the same element of $\Sigma \times \{0,1\}$.

6.7. **Proposition.** *For every cofibration* $f : (K/\!/\Sigma) \to (L/\!/\Sigma)$ *of labelled symmetric precubical sets, the maps* $f \star \gamma$ *and* $f \star \gamma^\epsilon$ *for* $\epsilon = 0, 1$ *are cofibrations as well. In other terms, the segment object* $(!^S(\Sigma \times \{0,1\})/\!/\Sigma)$ *is cartesian.*

Proof. The map $f \star \gamma : ((L/\!/\Sigma) \sqcup (L/\!/\Sigma)) \sqcup_{(K/\!/\Sigma) \sqcup (K/\!/\Sigma)} \mathrm{Cyl}(K/\!/\Sigma) \to \mathrm{Cyl}(L/\!/\Sigma)$ is a cofibration because for $n \geqslant 1$, the set map

$$(f \star \gamma)_n : (L_n \sqcup L_n) \sqcup_{K_n \sqcup K_n} (K_n \times \{0,1\}^n) \to L_n \times \{0,1\}^n$$

is one-to-one. Indeed, it consists of the inclusions $K_n \subset K_n \times \{0\}^n \subset L_n \times \{0\}^n \subset L_n \times \{0,1\}^n$ and $K_n \subset K_n \times \{1\}^n \subset L_n \times \{1\}^n \subset L_n \times \{0,1\}^n$. The map $f \star \gamma^\epsilon : (L/\!/\Sigma) \sqcup_{(K/\!/\Sigma)} \mathrm{Cyl}(K/\!/\Sigma) \to \mathrm{Cyl}(L/\!/\Sigma)$ with $\epsilon \in \{0,1\}$ is a cofibration because for $n \geqslant 1$, the map (with K_n embedded in $K_n \times \{\epsilon\}^n$ and L_n embedded in $L_n \times \{\epsilon\}^n$)

$$(f \star \gamma^\epsilon)_n : L_n \sqcup_{K_n} (K_n \times \{0,1\}^n) \longrightarrow L_n \times \{0,1\}^n$$

is one-to-one. Indeed, it consists of the inclusions $K_n \subset K_n \times \{\epsilon\}^n \subset L_n \times \{\epsilon\}^n \subset L_n \times \{0,1\}^n$. □

Hence the theorem:

6.8. **Theorem.** *There exists a unique combinatorial model category structure on* $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ *such that the class of cofibrations is generated by* $\mathcal{I}$ *and such that the fibrant objects are the* $\Lambda_{\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma}((!^S(\Sigma \times \{0,1\})/\!/\Sigma), \varnothing, \mathcal{I})$*-injective objects. All objects are cofibrant.*

7. REALIZING LABELLED PRECUBICAL SETS AS CUBICAL TRANSITION SYSTEMS

We want now to recall the construction of the realization functor from labelled symmetric precubical sets to cubical transition systems. Like for the exposition of the homotopy theory of cubical transition systems, this third paper of the series contains an improvement. We also explain in this section how to make this functor a Quillen functor by adding one generating cofibration to the model category of cubical transition systems.

7.1. **Notation.** $\mathrm{CUBE}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)$ *is the full subcategory of that of labelled symmetric precubical sets containing the labelled cubes* $\square_S[a_1,\dots,a_n]$ *with* $n \geqslant 0$ *and* $a_1,\dots,a_n \in \Sigma$.

7.2. **Notation.** $\mathrm{CUBE}(\mathbf{WHDTS})$ *is the full subcategory of that of weak higher dimensional transition systems containing the labelled cubes* $C_n[a_1,\dots,a_n]$ *with* $n \geqslant 0$ *and with* $a_1,\dots,a_n \in \Sigma$.

The following theorem is new and is an improvement of the theorem stated in [Gau10b].

7.3. **Theorem.** *There exists one and only one functor*

$$\mathbb{T} : \mathrm{CUBE}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \longrightarrow \mathrm{CUBE}(\mathbf{WHDTS})$$

such that $\mathbb{T}(\square_S[a_1,\dots,a_n]) := C_n[a_1,\dots,a_n]$ *for all* $n \geqslant 0$ *and all* $a_1,\dots,a_n \in \Sigma$ *and such that for any map of labelled symmetric precubical sets* $f : \square_S[a_1,\dots,a_m] \to \square_S[b_1,\dots,b_n]$, $\mathbb{T}(f)_0, f_0 : \{0,1\}^m \to \{0,1\}^n$ *are two equal set maps where* f_0 *is the set map induced by* f *between the set of* 0*-cubes and* $\mathbb{T}(f)_0$ *is the set map induced by* $\mathbb{T}(f)$ *between the set of states. Moreover this functor yields an isomorphism of categories*

$$\mathrm{CUBE}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \cong \mathrm{CUBE}(\mathbf{WHDTS}).$$

Sketch of proof. Let $m, n \geqslant 0$ and $a_1,\dots,a_m,b_1,\dots,b_n \in \Sigma$. A map of labelled symmetric precubical sets $f : \square_S[a_1,\dots,a_m] \to \square_S[b_1,\dots,b_n]$ gives rise to a set map $f_0 : \{0,1\}^m \to \{0,1\}^n$ from the set of states of $C_m[a_1,\dots,a_m]$ to the set of states of $C_n[b_1,\dots,b_n]$ which belongs to $\square_S([m],[n]) = \square_S^{op}\mathbf{Set}(\square_S[m],\square_S[n])$. By [Gau10b, Lemma 8.1], there exists a unique set map $\widehat{f} : \{1,\dots,n\} \to \{1,\dots,m\} \cup \{-\infty,+\infty\}$ such that $f_0(\epsilon_1,\dots,\epsilon_m) = (\epsilon_{\widehat{f}(1)},\dots,\epsilon_{\widehat{f}(n)})$ for every $(\epsilon_1,\dots,\epsilon_m) \in [m]$ with the conventions $\epsilon_{-\infty} = 0$ and $\epsilon_{+\infty} = 1$. Moreover, the restriction $\overline{f} : \widehat{f}^{-1}(\{1,\dots,m\}) \to \{1,\dots,m\}$ is a bijection. Since $f : \square_S[a_1,\dots,a_m] \to \square_S[b_1,\dots,b_n]$ is compatible with the labelling, one necessarily has $a_i = b_{\overline{f}^{-1}(i)}$ for every $i \in \{1,\dots,m\}$. One deduces a set map $\widetilde{f} : \{(a_1,1),\dots,(a_m,m)\} \to \{(b_1,1),\dots,(b_n,n)\}$ from the set of actions of $C_m[a_1,\dots,a_m]$ to the set of actions of $C_n[b_1,\dots,b_n]$ by setting $\widetilde{f}(a_i,i) = (b_{\overline{f}^{-1}(i)},\overline{f}^{-1}(i)) = (a_i,\overline{f}^{-1}(i))$. By [Gau10b, Lemma 8.2], if $f : \square_S[a_1,\dots,a_m] \to \square_S[b_1,\dots,b_n]$ and $g : \square_S[b_1,\dots,b_n] \to \square_S[c_1,\dots,c_p]$ are two maps of labelled symmetric precubical sets, then one has $\widehat{g\circ f} = \widehat{f}\circ\widehat{g}$. And by [Gau10b, Lemma 8.3], the two set maps f_0 and $\widetilde{f}$ above defined by starting from a map of labelled symmetric precubical sets $f : \square_S[a_1,\dots,a_m] \to \square_S[b_1,\dots,b_n]$ yield a map of weak higher dimensional transition systems $\mathbb{T}(f) : C_m[a_1,\dots,a_m] \to C_n[b_1,\dots,b_n]$. Hence the proof is complete with [Gau10b, Proposition 8.4] and [Gau10b, Theorem 8.5]. $\square$

7.4. **Theorem.** [Gau10b, Theorem 9.2] *There exists a unique colimit-preserving functor*

$$\mathbb{T} : {\square_S}^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{WHDTS}$$

extending the functor $\mathbb{T}$ *previously constructed on the full subcategory of labelled cubes. Moreover, this functor is a left adjoint.*

One has $\mathbb{T}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \subset \mathbf{CTS}$ since every colimit of cubes is cubical by [Gau11, Theorem 3.11] (see also [Gau10b, Proposition 9.8]). But we have the surprising negative result:

7.5. **Proposition.** *The restriction* $\mathbb{T} : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{CTS}$ *is not a left Quillen functor.*

Proof. Consider the cofibration $\partial\square_S[x,y] \subset \square_S[x,y]$ where x and y are two elements of Σ. The map of cubical transition systems $\mathbb{T}(\partial\square_S[x,y] \subset \square_S[x,y])$ is not a cofibration of cubical transition systems because the set of actions of $\mathbb{T}(\partial C_2[x,y])$ is the set with four elements $\{x_1, x_2, y_1, y_2\}$ with $\mu(x_1) = \mu(x_2) = x$ and $\mu(y_1) = \mu(y_2) = y$ and the set of actions of $\mathbb{T}(C_2[x,y])$ is the set with two elements $\{x, y\}$. $\square$

To overcome the problem, we are going to add the maps $\mathbb{T}(\partial\square_S[x,y] \subset \square_S[x,y])$ with $x, y \in \Sigma$ to the set of generating cofibrations of **CTS**. Surprisingly, the Olschok construction can be used again with the same segment object.

7.6. **Notation.** *Let* $\mathcal{I}^+ = \mathcal{I} \cup \{\mathbb{T}(\partial\square_S[x,y] \subset \square_S[x,y]) \mid x, y \in \Sigma\}$.

7.7. **Proposition.** *For any labelled symmetric precubical set* $(K//\Sigma)$*, one has*

$$\mathbb{T}((!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma)) = V \times \mathbb{T}((K//\Sigma)).$$

Proof. One can suppose without loss of generality that $K = \square_S[x_1, \dots, x_n]$ for $n \geqslant 0$ and $x_1, \dots, x_n \in \Sigma$ because all involved functors are colimit-preserving. For $n = 0$, the two members of the equality are isomorphic to the 1-state cubical transition system $\{()\}$. Now suppose that $n \geqslant 1$. The sets of states of the two members of the equality are equal to $\{0,1\}^n$. Since the two weak HDTS are cubical, all actions are used. So it suffices to check that the two members of the equality have the same set of transitions by using the fact that a cubical transition system is the union of its subcubes by Definition 3.8.

By the Yoneda lemma, the p-cubes of $(K//\Sigma)$ for $p \geqslant 1$ are in bijection with the maps of labelled symmetric precubical sets $\square_S[x_{\phi(1)}, \dots, x_{\phi(p)}] \to (K//\Sigma)$ where $\phi : \{1, \dots, p\} \to \{1, \dots, n\}$ is a one-to-one map. The image of the p-transition

$$(0_p, (x_{\phi(1)}, \phi(1)), \dots, (x_{\phi(p)}, \phi(p)), 1_p)$$

of $\mathbb{T}(\square_S[x_{\phi(1)}, \dots, x_{\phi(p)}]) = C_p[x_{\phi(1)}, \dots, x_{\phi(p)}]$ is a p-transition of the form [3]

$$((\alpha_1, \dots, \alpha_n), (x_{\phi(1)}, \phi(1)), \dots, (x_{\phi(p)}, \phi(p)), (\beta_1, \dots, \beta_n))$$

where $\alpha_i \leqslant \beta_i$ for all $i \in \{1, \dots, n\}$ with equality if and only if i does not belong to the image of ϕ.

Similarly, using the calculation in the proof of Proposition 6.2, the p-cubes of $(!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma)$ for $p \geqslant 1$ are in bijection with the maps of labelled symmetric precubical sets $\square_S[(x_{\phi(1)}, \epsilon_1), \dots, (x_{\phi(p)}, \epsilon_p)] \to (!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma)$ where $\phi : \{1, \dots, p\} \to \{1, \dots, n\}$ is a one-to-one map and where $\epsilon_1, \dots, \epsilon_p \in \{0,1\}$. The image of the p-transition

$$(0_p, (x_{\phi(1)}, \phi(1), \epsilon_1), \dots, (x_{\phi(p)}, \phi(p), \epsilon_p), 1_p)$$

of $\mathbb{T}(\square_S[(x_{\phi(1)}, \epsilon_1), \dots, (x_{\phi(p)}, \epsilon_p)]) = C_p[(x_{\phi(1)}, \epsilon_1), \dots, (x_{\phi(p)}, \epsilon_p)]$ is a p-transition of the form

$$((\alpha_1, \dots, \alpha_n), (x_{\phi(1)}, \phi(1), \epsilon_1), \dots, (x_{\phi(p)}, \phi(p), \epsilon_p), (\beta_1, \dots, \beta_n))$$

where $\alpha_i \leqslant \beta_i$ for all $i \in \{1, \dots, n\}$ with equality if and only if i does not belong to the image of ϕ. Since $(!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma)$ is cubical, it is equal to the union of its subcubes by Definition 3.8. So all transitions of $(!^S(\Sigma \times \{0,1\})//\Sigma) \times (K//\Sigma)$ are of the form above.

---

[3] Remember that a p-cube $C_p[u_1, \dots, u_p]$ has the set of actions $\{(u_1, 1), \dots, (u_p, p)\}$.

For similar reasons, the set of transitions of the cubical transition system $\mathbb{T}((K//\Sigma))$ consists of the tuples of the form

$$((\alpha_1,\dots,\alpha_n),(x_{\phi(1)},\phi(1)),\dots,(x_{\phi(p)},\phi(p)),(\beta_1,\dots,\beta_n))$$

with $\phi : \{1,\dots,p\} \to \{1,\dots,n\}$ one-to-one and where $\alpha_i \leqslant \beta_i$ for all $i \in \{1,\dots,n\}$ with equality if and only if i does not belong to the image of ϕ. Hence the set of transitions of $V \times \mathbb{T}((K//\Sigma))$ is equal to the one of $\mathbb{T}((!^S(\Sigma\times\{0,1\})//\Sigma)\times(K//\Sigma))$ by [Gau11, Proposition 5.5] (see also the description of the cylinder in the proof of [Gau11, Proposition 5.8]) and the proof is complete. □

7.8. **Proposition.** *The functor* $!^S : \mathbf{Set} \to \square_S^{op}\mathbf{Set}$ *of Proposition 5.4 induces a well-defined functor from* $\mathbf{Set}{\downarrow}\Sigma$ *to* $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$*. And one has the equality of functors*

$$\mathbb{T}\circ !^S = \mathbb{S} : \mathbf{Set}{\downarrow}\Sigma \to \mathbf{CTS}.$$

Proof. Let $\mu : L \to \Sigma$ be a set map. The two cubical transition systems $\mathbb{T}\circ !^S(L\to\Sigma)$ and $\mathbb{S}(L\to\Sigma)$ have, for any set map $L \to \Sigma$, the same set of states $\{0\}$, the same set of actions L, the same labelling map $L\to\Sigma$, and the same set of transitions $\{0\}\times\bigcup_{n\geqslant 1} L^n \times\{0\}$. Indeed, every n-transition $(0,u_1,\dots,u_n,0)$ is a transition of the image of $\mathbb{T}(\square_S[\mu(u_1),\dots,\mu(u_n)] \to !^S(L\to\Sigma))$ with $\mu(u_i)\mapsto u_i$. □

7.9. **Proposition.** *One has* $\mathbb{T}((!^S(\Sigma\times\{0,1\})//\Sigma)) = V$*. Moreover, for* $k=0,1$*, the image by* $\mathbb{T}$ *of the map of labelled symmetric precubical sets* $\gamma^k : \mathbf{1} \to (!^S(\Sigma\times\{0,1\})//\Sigma)$ *induced by* $\Sigma \cong \Sigma\times\{k\} \subset \Sigma\times\{0,1\}$ *is the map of cubical transition systems* $\mathbf{1}\to V$ *induced by* $\Sigma \cong \Sigma\times\{k\}\subset\Sigma\times\{0,1\}$ *as well.*

Proof. The equality $\mathbb{T}((!^S(\Sigma\times\{0,1\})//\Sigma)) = V$ comes from Proposition 7.8 applied to the projection map $\Sigma\times\{0,1\}\to\Sigma$. The last part about γ^k is a corollary of Proposition 7.8 as well applied to the set map $\Sigma\cong\Sigma\times\{k\}\subset\Sigma\times\{0,1\}$. □

We can now introduce the "augmented" model category structure of cubical transition systems.

7.10. **Theorem.** *There exists a unique combinatorial model category structure on* $\mathbf{CTS}$ *such that the set of maps* $\mathcal{I}^+$ *is the set of generating cofibrations and such that the fibrant objects are the* $\Lambda_{\mathbf{CTS}}(V,\varnothing,\mathcal{I}^+)$*-injective objects. All objects are cofibrant. This model category will be denoted by* $\mathbf{CTS}^+$*.*

Proof. The segment object V is still good with respect to the maps of $\mathcal{I}^+$ [4]. We already know that the segment object V is exponential. To prove that it is cartesian with respect to $\mathcal{I}^+$, we just have to prove that for any $x,y\in\Sigma$, $\mathbb{T}(f_{x,y})\star\gamma^k$ and $\mathbb{T}(f_{x,y})\star\gamma$ belong to $\mathbf{cof}_{\mathbf{CTS}}(\mathcal{I}^+)$ for $k=0,1$ and where $f_{x,y} : \partial\square_S[x,y]\subset\square_S[x,y]$ is the inclusion. By Proposition 6.7,

---

[4] The segment object V is not very good with respect to the maps of $\mathcal{I}^+$ because in the following diagram of solid arrows with $x,y\in\Sigma$

$$\begin{tikzcd}
\mathbb{T}(\partial\square_S[x,y]) \arrow[r] \arrow[d] & (!^S(\Sigma\times\{0,1\})//\Sigma) \\
\mathbb{T}(\square_S[x,y]) \arrow[ur, dashed, "k"] &
\end{tikzcd}$$

by imposing the set of actions of $\mathbb{T}(\partial\square_S[x,y])$ to be $\{(x,0),(x,1),(y,0),(y,1)\}$, the lift k cannot exist. The lift k would exist if and only if two opposite faces of the empty square $\mathbb{T}(\partial\square_S[x,y])$ were labelled by the same action.

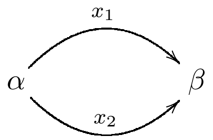

FIGURE 2. Cubical transition system $\mathrm{Cyl}(C_1[x])$ homotopy equivalent to the 1-cube $C_1[x]$ with $\mu(x_1) = \mu(x_2) = x$.

$f_{x,y} \star \gamma^k$ and $f_{x,y} \star \gamma$ are cofibrations of $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$. By Proposition 7.7 and Proposition 7.9, $\mathbb{T}(f_{x,y} \star \gamma^k) = \mathbb{T}(f_{x,y}) \star \gamma^k$ and $\mathbb{T}(f_{x,y} \star \gamma) = \mathbb{T}(f_{x,y}) \star \gamma$, hence the segment object V is cartesian with respect to $\mathcal{I}^+$. All cubical transition systems are still cofibrant for this new class of cofibrations. Hence the result by Theorem 2.5. $\square$

7.11. **Definition.** *A cubical transition system satisfies CSA1 (the* First Cattani-Sassone axiom*) if for every transition* (α, u, β) *and* (α, u', β) *such that the actions* u *and* u' *have the same label in* Σ*, one has* $u = u'$.

The full subcategory of cubical transition systems satisfying CSA1 is reflective by [Gau10b, Corollary 5.7]. The reflection is denoted by $\mathrm{CSA}_1 : \mathbf{CTS} \to \mathbf{CTS}$.

7.12. **Proposition.** *Let* T *be a cubical transition system satisfying CSA1. Let* I *and* S *be arbitrary sets of maps of* $\mathbf{CTS}$*. Then* T *is* $\Lambda_{\mathbf{CTS}}(V, S, I)$*-injective if and only if it is* S*-orthogonal.*

Proof. This is exactly [Gau11, Proposition 7.7]. It is stated in [Gau11] with $I = \mathcal{I}^{\mathbf{CTS}}$ being the choice made for the generating cofibrations of $\mathbf{CTS}$. But the contents of I does not play any role at all in the proof. $\square$

7.13. **Proposition.** *Every cubical transition system satisfying CSA1 is fibrant both in* $\mathbf{CTS}$ *and in* $\mathbf{CTS}^+$.

Proof. The first part is [Gau11, Proposition 7.8]. Every cubical transition system satisfying CSA1 is $\varnothing$-orthogonal, so fibrant in $\mathbf{CTS}^+$ as well by Proposition 7.12 and Theorem 7.10. $\square$

7.14. **Proposition.** *For every cubical transition system* X*, the unit* $X \to \mathrm{CSA}_1(X)$ *is a weak equivalence of both* $\mathbf{CTS}$ *and* $\mathbf{CTS}^+$.

Proof. The argument of the proof of [Gau11, Theorem 7.10] must be used: the unit $X \to \mathrm{CSA}_1(X)$ is a transfinite composition of pushouts of maps of the form $\sigma_{C_1[x]} : \mathrm{Cyl}(C_1[x]) \to C_1[x]$ (the source is depicted in Figure 2) with $x \in \Sigma$. Consider such a pushout:

$$\begin{tikzcd}
\mathrm{Cyl}(C_1[x]) \arrow[r, "\phi"] \arrow[d, "\sigma_{C_1[x]}"'] & X \arrow[d, "f"] \\
C_1[x] \arrow[r] \arrow[ur, phantom, "\ulcorner", very near end] & Y.
\end{tikzcd}$$

The map $\sigma_{C_1[x]}$ is *never* a cofibration of course. The point is that ϕ is either a cofibration of cubical transition systems or it takes the two actions of $\mathrm{Cyl}(C_1[x])$ to the same action of X:

in the first case, f is a weak equivalence in $\mathbf{CTS}$ and $\mathbf{CTS}^+$ because of the left properness; in the second case, f is just an isomorphism. $\square$

7.15. **Theorem.** *The two model categories* $\mathbf{CTS}$ *and* $\mathbf{CTS}^+$ *have the same class of weak equivalences: the class of maps of cubical transition systems* f *such that* $\mathrm{CSA}_1(f)$ *is an isomorphism.*

Proof. Two maps $f, g : X \to Y$ with Y satisfying CSA1 are homotopic with respect to the cylinder $V \times -$ if and only if they are equal by [Gau11, Proposition 7.4]. Therefore two weakly equivalent cubical transition systems in $\mathbf{CTS}$ or $\mathbf{CTS}^+$ satisfying CSA1 are isomorphic: this is [Gau11, Proposition 7.9]. The proof is complete with Proposition 7.14. $\square$

7.16. **Proposition.** *The functor* $\mathbb{T} : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{CTS}$ *preserves weak equivalences.*

Proof. Let $f : (K//\Sigma) \to (L//\Sigma)$ be a weak equivalence of labelled symmetric precubical sets. Let T be a fibrant object of the left determined model category structure of $\mathbf{CTS}$. We have to prove that the set map $\mathbf{CTS}(\mathbb{T}((L//\Sigma)), T)/{\simeq} \to \mathbf{CTS}(\mathbb{T}((K//\Sigma)), T)/{\simeq}$ induced by f is a bijection of sets where $\simeq$ means the homotopy relation induced by the cylinder of $\mathbf{CTS}$. By adjunction, we have to check that the set map

$$(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)((L//\Sigma), \mathbb{R}(T))/{\simeq} \longrightarrow (\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)((K//\Sigma), \mathbb{R}(T))/{\simeq}$$

induced by f is a bijection of sets where $\mathbb{R}$ is the right adjoint to $\mathbb{T}$. Since f is a weak equivalence of labelled symmetric precubical sets, it suffices to check that $\mathbb{R}(T)$ is $\Lambda_{\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma}((!^S(\Sigma \times \{0,1\})//\Sigma), \varnothing, \mathcal{I})$-injective. By Proposition 7.7 and Proposition 7.9, this is equivalent to T $\Lambda_{\mathbf{CTS}}(V, \varnothing, \mathcal{I})$-injective, which is the hypothesis. $\square$

7.17. **Corollary.** *There exists a zig-zag of left Quillen functors*

$$\begin{tikzcd} \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \arrow[r, "\mathbb{T}"] & \mathbf{CTS}^+ & \mathbf{CTS} \arrow[l, "\mathrm{Id}_{\mathbf{CTS}}"'] \end{tikzcd}.$$

Moreover, the right-hand left Quillen functor induces a Quillen equivalence $\mathbf{CTS} \simeq \mathbf{CTS}^+$.

Proof. The functor $\mathbb{T} : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{CTS}^+$ is a left Quillen functor by Proposition 7.15 and Proposition 7.16 and by definition of the cofibrations of $\mathbf{CTS}^+$. The functor $\mathrm{CSA}_1 : \mathbf{CTS} \to \mathbf{CTS}$ is a cofibrant-fibrant replacement for the two model categories $\mathbf{CTS}$ and $\mathbf{CTS}^+$ by Proposition 7.13 and by Proposition 7.14. They have the same class of weak equivalences so the left Quillen functor $\mathbf{CTS} \to \mathbf{CTS}^+$ induces an adjoint equivalence of categories between the homotopy categories. $\square$

8. Homotopical property of the realization functor

We are now ready to compare labelled symmetric precubical sets and cubical transition systems from a homotopy point of view.

8.1. **Notation.** *Let* $\mathcal{S} = \{p_x : C_1[x] \sqcup C_1[x] \to \uparrow x \uparrow \mid x \in \Sigma\}$.

Let X be a cubical transition system. Let us factor in $\mathbf{CTS}$ the canonical map $X \to \mathbf{1}$ as a composite $X \to \underline{\mathbf{L}}_{\mathcal{S}}(X) \to \mathbf{1}$ where the left-hand map belongs to $\mathbf{cell}_{\mathbf{CTS}}(\mathcal{S})$ and the right-hand map belongs to $\mathbf{inj}_{\mathbf{CTS}}(\mathcal{S})$. The functor $\underline{\mathbf{L}}_{\mathcal{S}} : \mathbf{CTS} \to \mathbf{CTS}$ is studied in [Gau11]. The next proposition explains the effect of the functor $\underline{\mathbf{L}}_{\mathcal{S}}$.

8.2. **Proposition.** *For a cubical transition system* $X = (S, \mu : L \to \Sigma, T = \bigcup_{n \geqslant 1} T_n)$*, the following facts are equivalent:*

(1) *The labelling map* μ *is one-to-one.*
(2) X *is* $\mathcal{S}$*-injective.*
(3) X *is* $\mathcal{S}$*-orthogonal.*

If one of these facts is true, then X *satisfies CSA1.*

Proof. The equivalence (2) $\Leftrightarrow$ (3) is due to the fact that all maps of $\mathcal{S}$ are epimorphisms. Let us suppose (2). Let x_1 and x_2 be two actions of X with $\mu(x_1) = \mu(x_2) = x$. Since X is injective with respect to $\underline{x_i} \to C_1[x]$ for $i = 1, 2$, the two maps $\underline{x_i} \subset X$ factors as a composite $\underline{x_i} \to C_1[x] \to X$. Hence there is a map $C_1[x] \sqcup C_1[x] \to X$ sending one action of the source to x_1 and the other one to x_2. By hypothesis, X is p_x-injective. Therefore the latter map factors as a composite $C_1[x] \sqcup C_1[x] \to \uparrow x \uparrow \to X$. So $x_1 = x_2$, and μ is one-to-one. Conversely, suppose that μ is one-to-one. Let $C_1[x] \sqcup C_1[x] \to X$ be a map. Then the two actions of the source are taken to the same action of X because they have the same labelling. Therefore the map factors as a composite $C_1[x] \sqcup C_1[x] \to \uparrow x \uparrow \to X$. The last assertion is obvious. ☐

So the functor $\underline{\mathbf{L}}_{\mathcal{S}} : \mathbf{CTS} \to \mathbf{CTS}$ induces a functor from $\mathbf{CTS}$ to the full reflective subcategory $\mathcal{S}^{\perp}$ of cubical transition systems consisting of $\mathcal{S}$-orthogonal objects. By [Gau11, Theorem 8.11], the functor $\underline{\mathbf{L}}_{\mathcal{S}}$ is left adjoint to the inclusion functor $\iota_{\mathcal{S}} : \mathcal{S}^{\perp} \subset \mathbf{CTS}$.

8.3. **Proposition.** *Every cubical transition system of the form* $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ *where* X *is a cubical transition system is fibrant in* $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$*.*

Proof. The proposition is stated only for the reader's convenience because it is already proved in [Gau11, Theorem 8.11]. A cubical transition system of the form $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is $\mathcal{S}$-orthogonal and satisfies CSA1 by Proposition 8.2, so it is fibrant in $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$ by Proposition 7.12 and by Corollary 4.7. ☐

8.4. **Proposition.** *Every cubical transition system of the form* $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ *where* X *is a cubical transition system is fibrant in* $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^{+})$*.*

Proof. The proof of this fact is a little bit delicate because the segment object V is not very good with respect to $\mathcal{I}^{+}$[4]. In such a situation, the Olschok construction only provides information about the Bousfield localization of $\mathbf{CTS}^{+}$ with respect to the set of maps $\Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})$ by [Ols09a, Lemma 4.4] where $\mathcal{S}^{cof}$ is a set of cofibrant replacements in $\mathbf{CTS}^{+}$ of the maps of $\mathcal{S}$. By the universal property of the Bousfield localization [Hir03, Theorem 3.1.6], and because $\mathcal{S}^{cof} \subset \Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})$, the left Quillen functor $\mathbf{CTS}^{+} \to \underline{\mathbf{L}}_{\Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})}(\mathbf{CTS}^{+})$ induced by the identity functor induces a left Quillen functor

$$\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^{+}) \longrightarrow \underline{\mathbf{L}}_{\Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})}(\mathbf{CTS}^{+}).$$

So it suffices to prove that $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is fibrant in $\underline{\mathbf{L}}_{\Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})}(\mathbf{CTS}^{+})$ for every cubical transition system X. By Theorem 2.5, it suffices to prove that $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is $\Lambda_{\mathbf{CTS}}(V, \mathcal{S}^{cof}, \mathcal{I}^{+})$-injective, and by Proposition 8.2 and Proposition 7.12, it suffices to prove that $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is $\mathcal{S}^{cof}$-orthogonal.

It is now time to describe explicitly a cofibrant replacement of $p_x : C_1[x] \sqcup C_1[x] \to \uparrow x \uparrow$ in $\mathbf{CTS}^{+}$. The functor $V \times -$ is described in [Gau11, Proposition 5.5] and in [Gau11, Proposition 5.8]. The cubical transition system $V \times C_1[x]$ has the same state as $C_1[x]$ (one initial state α and one final state β), has two actions x_1 and x_2 labelled by x and two 1-transitions (α, x_1, β) and (α, x_2, β) (Figure 2). A cofibrant replacement of p_x can then be obtained by considering the composite map

$$p_x^{cof} : C_1[x] \sqcup C_1[x] \to (V \times C_1[x] \sqcup V \times C_1[x]) \to (V \times C_1[x] \sqcup V \times C_1[x])/(x_2 = x_4 = x)$$

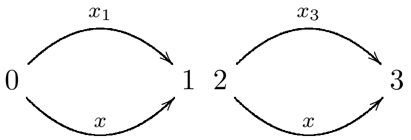

FIGURE 3. $(V \times C_1[x] \sqcup V \times C_1[x])/(x_2 = x_4 = x)$.

where $\{x_1, x_2\}$ is the set of actions of the left-hand copy of $V \times C_1[x]$ and where $\{x_3, x_4\}$ is the set of actions of the right-hand copy of $V \times C_1[x]$. To completely determine this map, we must say that it induces a bijection on the set of states and it is the inclusion $\{x_1, x_3\} \subset \{x_1, x_3, x\}$ on actions with $\mu(x_1) = \mu(x_2) = \mu(x_3) = \mu(x_4) = x$. So p_x^{cof} is a cofibration. The target of p_x^{cof} is depicted in Figure 3. One has the equalities of cubical transition systems

$$\mathrm{CSA}_1\left[(V \times C_1[x] \sqcup V \times C_1[x])/(x_2 = x_4 = x)\right] = \uparrow x \uparrow = \mathrm{CSA}_1(\uparrow x \uparrow).$$

Therefore, using Theorem 7.15, the cubical transition systems $(V \times C_1[x] \sqcup V \times C_1[x])/(x_2 = x_4 = x)$ and $\uparrow x \uparrow$ are weakly equivalent in $\mathbf{CTS}^+$. Thus, p_x^{cof} is a cofibrant replacement of p_x.

We are supposed to check that $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is p_x^{cof}-orthogonal for all $x \in \Sigma$ to complete the proof. Consider a commutative diagram of solid arrows:

$$\begin{tikzcd}
C_1[x] \sqcup C_1[x] \arrow[rr] \arrow[d, "p_x^{cof}"'] & & \underline{\mathbf{L}}_{\mathcal{S}}(X) \arrow[d] \\
(V \times C_1[x] \sqcup V \times C_1[x])/(x_2 = x_4 = x) \arrow[rr] \arrow[urr, dashed, "k"] & & \mathbf{1}
\end{tikzcd}$$

Remember by Proposition 8.2 that the labelling map of $\underline{\mathbf{L}}_{\mathcal{S}}(X)$ is one-to-one. The existence and uniqueness of the lift k is then clear on states (because p_x^{cof} is bijective on states) and on actions (k takes all actions of its source to x). □

8.5. **Proposition.** *For every cubical transition system X, the unit $X \to \underline{\mathbf{L}}_{\mathcal{S}}(X)$ is a weak equivalence of both $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$ and $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$.*

Proof. The map $X \to \underline{\mathbf{L}}_{\mathcal{S}}(X)$ is a transfinite composition of pushouts of maps of $\mathcal{S}$. Then we can use the argument [Gau11, Proposition 8.5]. Let us briefly recall it. Consider a pushout in $\mathbf{CTS}$ of the form (with $x \in \Sigma$)

$$\begin{tikzcd}
C_1[x] \sqcup C_1[x] \arrow[r, "\phi"] \arrow[d, "p_x"'] & X \arrow[d, "f"] \\
\uparrow x \uparrow \arrow[r] & Y. \arrow[ul, phantom, "\ulcorner", very near start]
\end{tikzcd}$$

The map p_x is *never* a cofibration of course. The point is that ϕ is either a cofibration or it takes the two actions of $C_1[x] \sqcup C_1[x]$ to the same action of X: in the first case, f is a weak equivalence in $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$ and $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ because of the left properness; in the second case, f is just an isomorphism. □

8.6. **Theorem.** *The two model categories* $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$ *and* $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ *have the same class of weak equivalences: the class of maps of cubical transition systems* f *such that* $\underline{\mathbf{L}}_{\mathcal{S}}(f)$ *is an isomorphism.*

Proof. By Proposition 8.3, Proposition 8.4 and Proposition 8.5, the functor $\underline{\mathbf{L}}_{\mathcal{S}} : \mathbf{CTS} \to \mathbf{CTS}$ is a cofibrant-fibrant replacement both in $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$ and $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$. A map f is a weak equivalence in the Bousfield localization if and only if $\underline{\mathbf{L}}_{\mathcal{S}}(f)$ is a weak equivalence of $\mathbf{CTS}$ (or of $\mathbf{CTS}^+$) by [Hir03, Theorem 3.2.13]. But the source and target of $\underline{\mathbf{L}}_{\mathcal{S}}(f)$ satisfy CSA1 by Proposition 8.2, hence the conclusion using Theorem 7.15. □

8.7. **Corollary.** *The left Quillen functor* $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}) \to \underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ *induced by the identity functor is a Quillen equivalence.*

Proof. The left Quillen functor $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}) \to \underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ induces an adjoint equivalence of categories between the homotopy categories. □

Before stating the next theorem, we need to introduce again a few notations.

8.8. **Definition.** *Let* $X \in \mathbf{WHDTS}$*. The* cubification functor *is the functor*

$$\underline{\mathrm{Cub}} : \mathbf{WHDTS} \longrightarrow \mathbf{WHDTS}$$

defined by

$$\underline{\mathrm{Cub}}(X) = \varinjlim_{C_n[x_1,\dots,x_n]\to X} C_n[x_1,\dots,x_n],$$

the colimit being taken in $\mathbf{CTS}$ *(or equivalently in* $\mathbf{WHDTS}$*).*

We can now prove one of the main result of this paper:

8.9. **Theorem.** *There exists a Bousfield localization of* $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ *which is Quillen equivalent to the Bousfield localization of the left determined model category structure of* $\mathbf{CTS}$ *by the cubification functor.*

Proof. By [Gau11, Corollary 8.7], the Bousfield localization of the left determined model category structure of $\mathbf{CTS}$ by the cubification functor is $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$. By Corollary 8.7 and [Dug01, Proposition 3.2], it suffices to prove that the left Quillen functor $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ induced by $\mathbb{T}$ is homotopically surjective in the sense of [Dug01, Definition 3.1].

The right adjoint $\mathbb{R} : \mathbf{CTS}^+ \to \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ of $\mathbb{T} : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{CTS}^+$ may be defined as follows. Let X be a cubical transition system. The set $\mathbb{R}(X)$ of n-cubes labelled by $(a_1,\dots,a_n) \in \Sigma^n$ is the set of maps of cubical transition systems $C_n[a_1,\dots,a_n] \to X$ (so for $n = 0$, it is the set of states) with an obvious definition of the face maps and symmetry maps. Using the isomorphism of categories $\mathrm{CUBE}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \cong \mathrm{CUBE}(\mathbf{WHDTS})$ by Theorem 7.3, one deduces that $\mathbb{T}(\mathbb{R}(X)) \cong \underline{\mathrm{Cub}}(X)$. Hence by [Gau11, Proposition 8.4] and by [Gau11, Proposition 8.5], for any cubical transition system X, the counit $\mathbb{T}(\mathbb{R}(X)) \to X$ is a weak equivalence of $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS})$, and therefore of $\underline{\mathbf{L}}_{\mathcal{S}}(\mathbf{CTS}^+)$ by Theorem 8.6 [5]. Since all cubical transition systems are cofibrant, we see that the last assertion is nothing else but the definition of homotopically surjective. □

---

[5] [Gau11, Proposition 8.4] actually proves that the counit $\underline{\mathrm{Cub}}(X) \to X$ is a transfinite composition of pushouts of the maps $p_x : C_1[x] \sqcup C_1[x] \to \uparrow x \uparrow$ for $x \in \Sigma$; so $\underline{\mathrm{Cub}}(X) \to X$ is a weak equivalence in the Bousfield localizations by the same argument as for proving Proposition 8.5.

For $K = \square_S[x_1,\dots,x_n] \sqcup_{\partial\square_S[x_1,\dots,x_n]} \square_S[x_1,\dots,x_n]$ with $n \geqslant 2$ and $x_1,\dots,x_n \in \Sigma$, $\mathbb{R}(\underline{\mathbf{L}}_{\mathcal{S}}(\mathbb{T}(K))) = \square_n[x_1,\dots,x_n]$ by Proposition 8.2 and [Gau10b, Proposition 9.3]. This suggests to recall now the HDA paradigm for a slight improvement of Theorem 8.9.

9. The higher dimensional automata paradigm

9.1. **Definition.** [Gau10b, Definition 7.1] *A labelled symmetric precubical set* $(K//\Sigma)$ *satisfies* the paradigm of higher dimensional automata (HDA paradigm) *if for every* $p \geqslant 2$*, every commutative square of solid arrows (called a* labelled p-shell *or* labelled p-dimensional shell*)*

$$\begin{tikzcd}
\partial\square_S[p] \arrow[r] \arrow[d] & K \arrow[d] \\
\square_S[p] \arrow[r] \arrow[ur, dashed, "k"] & !^S\Sigma
\end{tikzcd}$$

admits at most one lift k *(i.e. a map* k *making the two triangles commutative).*

The interest of the HDA paradigm in computer science is that it is satisfied by all real examples (see for example [Gau08, Theorem 5.2] and [Gau08, Corollary 5.3]). A full n-cube with $n \geqslant 2$ models the concurrent execution of n actions. An empty n-cube with $n \geqslant 2$ models the concurrent execution of $n-1$ actions maximum among a set of n actions [Gau08]. It is impossible to have two n-cubes (for $n \geqslant 2$) with the same boundary. Either it is possible for the n actions to run concurrently (full), or there is an obstruction (empty).

Note that the HDA paradigm is automatically satisfied by higher dimensional transition systems because for $n \geqslant 2$, there is the isomorphism

$$C_n[x_1,\dots,x_n] \sqcup_{\partial C_n[x_1,\dots,x_n]} C_n[x_1,\dots,x_n] \cong C_n[x_1,\dots,x_n]$$

for all $x_1,\dots,x_n \in \Sigma$ by [Gau10b, Proposition 9.3].

By [Gau10b, Proposition 7.3], the HDA paradigm is equivalent to being orthogonal to the set of maps $\left\{\square_S[a_1,\dots,a_p] \sqcup_{\partial\square_S[a_1,\dots,a_p]} \square_S[a_1,\dots,a_p] \to \square_S[a_1,\dots,a_p]\right\}$ for $p \geqslant 2$ and $a_1,\dots,a_p \in \Sigma$. So (see [Gau10b, Corollary 7.4]), the full subcategory, denoted by $\mathbf{HDA}^\Sigma$, of $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ containing the objects satisfying the HDA paradigm is a full reflective locally presentable category of the category $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ of labelled symmetric precubical sets. In other terms, the inclusion functor $i_\Sigma : \mathbf{HDA}^\Sigma \subset \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ has a left adjoint $\mathrm{Sh}_\Sigma : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{HDA}^\Sigma$.

In fact the category $\mathbf{HDA}^\Sigma$ is locally finitely presentable; indeed, the labelled n-cubes for $n \geqslant 0$ are in $\mathbf{HDA}^\Sigma$ by [Gau10b, Proposition 7.2], and one can prove that they form a dense set of generators.

9.2. **Notation.** *When* Σ *is the singleton* $\{\tau\}$*, let* $i := i_\Sigma$ *and* $\mathrm{Sh} := \mathrm{Sh}_\Sigma$*.*

One has $i_\Sigma(K//\Sigma) \cong (i(K)//\Sigma) = (K//\Sigma)$ and $\mathrm{Sh}_\Sigma(K//\Sigma) \cong (\mathrm{Sh}(K) \to \mathrm{Sh}(!^S\Sigma) \cong !^S\Sigma)$ because the symmetric precubical set $!^S\Sigma$ belongs to $\mathbf{HDA}$.

We want to restrict the homotopy theory of labelled symmetric precubical sets to the full reflective subcategory $\mathbf{HDA}^\Sigma$. So we must explain how to restrict the Olschok construction to a full reflective subcategory, at least within our particular setting.

9.3. **Theorem.** *(*[Ols09a, Lemma 5.2] *with some additional remarks) (Restriction to a full reflective subcategory) Let $\mathcal{K}$, I, S and V as in Theorem 2.5. Let $\mathcal{A}$ be a full reflective locally presentable subcategory with $V \in \mathcal{A}$ and $I \subset \mathrm{Mor}(\mathcal{A})$. Let $R : \mathcal{K} \to \mathcal{A}$ be the reflection. Suppose that $S \subset \mathbf{cof}_{\mathcal{A}}(I)$ and that for every object $X \in \mathcal{A}$, $X^V \in \mathcal{A}$ where $(-)^V$ is the right adjoint in $\mathcal{K}$ to the cylinder functor $\mathrm{Cyl}(-) = V \times -$. Then there exists a unique combinatorial model category structure such that the class of cofibrations is generated by I and such that an object of $\mathcal{A}$ is fibrant if and only if it is $\Lambda_{\mathcal{K}}(V, S, I)$-injective. In particular, the fibrant objects of $\mathcal{A}$ are the fibrant objects of $\mathcal{K}$ belonging to $\mathcal{A}$. The reflection $R : \mathcal{K} \to \mathcal{A}$ is a homotopically surjective left Quillen adjoint. All objects are cofibrant.*

Proof. The inclusion functor $\mathcal{A} \subset \mathcal{K}$ is a right adjoint, therefore it preserves binary products. And $V \in \mathcal{A}$ by hypothesis. Hence $V \times - : \mathcal{K} \to \mathcal{K}$ restricts to an endofunctor of $\mathcal{A}$.

Note that $I \subset \mathcal{A}$ implies that $I = R(I)$. One has $\mathbf{inj}_{\mathcal{A}}(I) = \mathrm{Mor}(\mathcal{A}) \cap \mathbf{inj}_{\mathcal{K}}(I)$ because $\mathcal{A}$ is a full subcategory. So for all $f \in \mathbf{inj}_{\mathcal{A}}(I)$, $(\varnothing \to A)\square f$ for every object A of $\mathcal{A}$ because $(\mathbf{cof}_{\mathcal{K}}(I), \mathbf{inj}_{\mathcal{K}}(I))$ is a cofibrant small weak factorization system, hence $(\mathbf{cof}_{\mathcal{A}}(I), \mathbf{inj}_{\mathcal{A}}(I))$ is a cofibrant small weak factorization system of $\mathcal{A}$.

Since R is colimit-preserving, $R(\mathbf{cell}_{\mathcal{K}}(I)) \subset \mathbf{cell}_{\mathcal{A}}(I)$. Every map of $\mathbf{cof}_{\mathcal{K}}(I)$ is a retract of a map of $\mathbf{cell}_{\mathcal{K}}(I)$, therefore $R(\mathbf{cof}_{\mathcal{K}}(I)) \subset \mathbf{cof}_{\mathcal{A}}(I)$. Let $f \in \mathrm{Mor}(\mathcal{A}) \cap \mathbf{cof}_{\mathcal{K}}(I)$. Then $R(f) = f \in \mathbf{cof}_{\mathcal{A}}(I)$. One obtains the inclusion $\mathrm{Mor}(\mathcal{A}) \cap \mathbf{cof}_{\mathcal{K}}(I) \subset \mathbf{cof}_{\mathcal{A}}(I)$. Let $A \in \mathcal{A}$. Then $A \sqcup A \to V \times A$ is a map of $\mathcal{A}$ belonging to $\mathbf{cof}_{\mathcal{K}}(I)$ because V is good in $\mathcal{K}$. So V is good in $\mathcal{A}$ as well.

Let $A, B \in \mathcal{A}$. Then $\mathcal{A}(V \times A, B) \cong \mathcal{K}(V \times A, B) \cong \mathcal{K}(A, B^V) \cong \mathcal{A}(A, B^V)$ because $B^V \in \mathcal{A}$ and because $\mathcal{A}$ is a full subcategory of $\mathcal{K}$. So the segment object V is exponential in $\mathcal{A}$. Since R is colimit-preserving, one has $I \star \gamma \in R(\mathbf{cof}_{\mathcal{K}}(I)) \subset \mathbf{cof}_{\mathcal{A}}(I)$ and $I \star \gamma^k \in R(\mathbf{cof}_{\mathcal{K}}(I)) \subset \mathbf{cof}_{\mathcal{A}}(I)$, hence V is cartesian in $\mathcal{A}$ as well.

Let T be an object of $\mathcal{A}$. Then T is $\Lambda_{\mathcal{K}}(V, S, I)$-injective, if and only if it is $\Lambda_{\mathcal{A}}(V, S, I)$-injective because $R(\Lambda_{\mathcal{K}}(V, S, I)) = \Lambda_{\mathcal{A}}(V, S, I)$. So the fibrant objects of $\mathcal{A}$ are the fibrant objects of $\mathcal{K}$ belonging to $\mathcal{A}$. Hence the existence of the model category structure on $\mathcal{A}$ by Theorem 2.5.

Since $R(\mathbf{cof}_{\mathcal{K}}(I)) \subset \mathbf{cof}_{\mathcal{A}}(I)$, the reflection R takes cofibrations to cofibrations. Let f be a weak equivalence of $\mathcal{K}$. Let T be a fibrant object of $\mathcal{A}$. Then $\mathcal{K}(f, T)/\simeq$ is a bijection. By adjunction, one gets that $\mathcal{A}(R(f), T)/\simeq$ is a bijection as well, i.e. that $R(f)$ is a weak equivalence of $\mathcal{A}$. Therefore the reflection $R : \mathcal{K} \to \mathcal{A}$ is a left Quillen adjoint. It is homotopically surjective because for any fibrant object $A \in \mathcal{A}$, A is cofibrant in $\mathcal{K}$ and there is the isomorphism $R(A) \cong A$. □

Denote by $(K/\!/\Sigma) \mapsto (K/\!/\Sigma)^{(!^S(\Sigma\times\{0,1\})/\!/\Sigma)}$ the right adjoint to the cylinder functor of $\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma$ which exists by Proposition 6.2.

9.4. **Proposition.** *For every labelled symmetric precubical set $(K/\!/\Sigma)$, if $(K/\!/\Sigma)$ satisfies the HDA paradigm, then $(K/\!/\Sigma)^{(!^S(\Sigma\times\{0,1\})/\!/\Sigma)}$ satisfies the HDA paradigm as well.*

Proof. We have to prove that there exists at most one lift k for every commutative diagram of the form of Figure 4 with $p \geqslant 2$ and $a_1, \dots, a_p \in \Sigma$. By adjunction, that means that we have to prove that there exists at most one list $\overline{f}$ for every commutative diagram of the form of Figure 5.

$$\begin{tikzcd}
\partial\square_S[a_1,\dots,a_p] \arrow[r, "f"] \arrow[d] & (K//\Sigma)^{(!^S(\Sigma\times\{0,1\})//\Sigma)} \\
\square_S[a_1,\dots,a_p] \arrow[ur, dashed, "\overline{f}"] &
\end{tikzcd}$$

FIGURE 4. $(K//\Sigma)^{(!^S(\Sigma\times\{0,1\})//\Sigma)}$ must satisfy the HDA paradigm.

$$\begin{tikzcd}
\mathrm{Cyl}(\partial\square_S[a_1,\dots,a_p]) \arrow[r, "f"] \arrow[d] & K \\
\mathrm{Cyl}(\square_S[a_1,\dots,a_p]). \arrow[ur, dashed, "\overline{f}"] &
\end{tikzcd}$$

FIGURE 5. HDA paradigm for $(K//\Sigma)^{(!^S(\Sigma\times\{0,1\})//\Sigma)}$ and adjunction.

One has

$$\begin{aligned}(\mathrm{Cyl}(\partial\square_S[a_1,\dots,a_p]))_0 = (\partial\square_S[a_1,\dots,a_p])_0 \cong (\square_S[a_1,\dots,a_p])_0 \\ = (\mathrm{Cyl}(\square_S[a_1,\dots,a_p]))_0\end{aligned}$$

and

$$\begin{aligned}(\mathrm{Cyl}(\partial\square_S[a_1,\dots,a_p]))_1 = (\partial\square_S[a_1,\dots,a_p])_1 \times \{0,1\} \\ \cong (\square_S[a_1,\dots,a_p])_1 \times \{0,1\} = (\mathrm{Cyl}(\square_S[a_1,\dots,a_p]))_1.\end{aligned}$$

Therefore $\overline{f}_0 = f_0$ and $\overline{f}_1 = f_1$ exist and are unique.

The fact that $(K//\Sigma)$ satisfies the HDA paradigm is going to be used only now. Let $x \in (\mathrm{Cyl}(\square_S[a_1,\dots,a_p]))_p$ with $p \geqslant 2$. Since

$$\mathrm{Cyl}(\square_S[a_1,\dots,a_p]))_p = (\square_S[a_1,\dots,a_p]))_p \times \{0,1\}^p$$

one sees that all $\overline{f}(\partial_i^\alpha x) = f(\partial_i^\alpha x)$ are determined and the proof is complete. $\square$

Hence the theorem:

9.5. **Theorem.** *There exists a unique combinatorial model category structure on* $\mathbf{HDA}^\Sigma$ *such that the class of cofibrations is generated by* $\mathcal{I}$ *and such that a fibrant object is a* $\Lambda_{\square_S^{op}\mathbf{Set}\downarrow !^S\Sigma}((!^S(\Sigma\times\{0,1\})//\Sigma),\varnothing,\mathcal{I})$*-injective object of* $\mathbf{HDA}^\Sigma$*. All objects are cofibrant.*

Now we can state the last theorem:

9.6. **Theorem.** *There exists a Bousfield localization of* $\mathbf{HDA}^\Sigma$ *which is Quillen equivalent to the Bousfield localization of the left determined model category structure of* **CTS** *by the cubification functor.*

Proof. By [Gau10b, Theorem 9.5], the functor $\mathbb{T} : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{WHDTS}$ factors uniquely (up to isomorphism of functors) as a composite

$$\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \xrightarrow{\mathrm{Sh}_\Sigma} \mathbf{HDA}^\Sigma \xrightarrow{\overline{\mathbb{T}}} \mathbf{WHDTS}.$$

Moreover, the functor $\overline{\mathbb{T}}$ is a left adjoint. And it is not a left Quillen adjoint with exactly the same proof as for Proposition 7.5. We work with the left Quillen functor $\overline{T} : \mathbf{HDA}^\Sigma \to \underline{\mathbf{L}}_\mathcal{S}(\mathbf{CTS}^+)$ like in the proof of Theorem 8.9. We then just have to check that the functor $\overline{\mathbb{T}}$ is, like the functor $\mathbb{T}$, homotopically surjective.

Let X be a cubical transition system. Let $n \geqslant 2$ and $x_1, \dots, x_n \in \Sigma$. Then one has $(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)(\square_n[x_1, \dots, x_n], \mathbb{R}(X)) \cong \mathbf{CTS}(\mathbb{T}(\square_n[x_1, \dots, x_n]), X)$ by the adjunction $\mathbb{T} \dashv \mathbb{R}$, and

$$\begin{aligned}\mathbf{CTS}(\mathbb{T}(\square_S[x_1, \dots, x_n]), X) &= \mathbf{CTS}(\mathbb{T}(\square_S[x_1, \dots, x_n] \sqcup_{\partial\square_S[x_1,\dots,x_n]} \square_S[x_1, \dots, x_n]), X)\\ &\cong \mathbf{CTS}(\mathbb{T}(\square_S[x_1, \dots, x_n]), X) \sqcup_{\mathbf{CTS}(\mathbb{T}(\partial\square_S[x_1,\dots,x_n]),X)} \mathbf{CTS}(\mathbb{T}(\square_S[x_1, \dots, x_n]), X)\end{aligned}$$

by [Gau10b, Proposition 9.3] and because the contravariant functor $\mathbf{CTS}(-, X)$ is limit-preserving. So by the adjunction $\mathbb{T} \dashv \mathbb{R}$ again and because the contravariant functor

$$(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)(-, X)$$

is limit-preserving, one obtains the bijection

$$\begin{aligned}&(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)(\square_n[x_1, \dots, x_n], \mathbb{R}(X))\\ &\qquad\cong (\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma)(\square_S[x_1, \dots, x_n] \sqcup_{\partial\square_S[x_1,\dots,x_n]} \square_S[x_1, \dots, x_n], \mathbb{R}(X)),\end{aligned}$$

which means that $\mathbb{R}(X) \in \mathbf{HDA}^\Sigma$. Therefore $\overline{\mathbb{T}}(\mathbb{R}(X)) \cong \mathbb{T}(\mathbb{R}(X)) \cong \underline{\mathrm{Cub}}(X)$. $\square$

The reflection $\mathrm{Sh}_\Sigma : \square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma \to \mathbf{HDA}^\Sigma$ is a homotopically surjective left Quillen functor by Theorem 9.3. So, by [Dug01, Proposition 3.2] there exists a set of maps $\mathcal{Y}$ and a Quillen equivalence

$$\mathrm{Sh}_\Sigma : \underline{\mathbf{L}}_\mathcal{Y}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \simeq \mathbf{HDA}^\Sigma.$$

From Theorem 9.6, there exists a set of maps $\mathcal{X}$ and a Quillen equivalence

$$\overline{\mathbb{T}} : \underline{\mathbf{L}}_\mathcal{X}\,\mathbf{HDA}^\Sigma \simeq \underline{\mathbf{L}}_{\underline{\mathrm{Cub}}}(\mathbf{CTS}).$$

One obtains the Quillen equivalence $\underline{\mathbf{L}}_\mathcal{X}\,\underline{\mathbf{L}}_\mathcal{Y}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \simeq \underline{\mathbf{L}}_{\underline{\mathrm{Cub}}}(\mathbf{CTS})$. Hence

$$\mathbb{T} : \underline{\mathbf{L}}_{\mathcal{X}\cup\mathcal{Y}}(\square_S^{op}\mathbf{Set}{\downarrow}!^S\Sigma) \simeq \underline{\mathbf{L}}_{\underline{\mathrm{Cub}}}(\mathbf{CTS}).$$
